1 Introduction to this document and (very much) shortened version history

This is 1.3f of 2019/09/10.

Please refer to [CHANGES.pdf](#) or [CHANGES.html](#).

Internet: <http://mirrors.ctan.org/macros/generic/xint/CHANGES.html>

We keep here only a brief timeline of the most important changes.

At 1.3e the indices which were added at 1.3c got removed: their inclusion caused extra time in the build of [sourcexint.pdf](#), larger file size, and the macros created using `\csname...\endcsname` were not indexed, of course the indexing of functions would have needed systematic extra mark-up. Besides their functionality is advantageously made available via the search function in PDF viewers. Already the local tables of contents are useful enough most of the time when one searches something.

- Release 1.3f of 2019/09/10: starred variant `\xintDigits*`.
- Release 1.3e of 2019/04/05: `xinttrig`, `xintlog`, `\xintdefefunc` ``non-protected'' variant of `\xintdeffunc`.
Indices removed from [sourcexint.pdf](#).
- Release 1.3d of 2019/01/06: bugfix of 1.2p bug for division with a zero dividend and a one-digit divisor, `\xinteval` et al. wrappers, `gcd()` and `lcm()` work with fractions.
- Release 1.3c of 2018/06/17: documentation better hyperlinked, [sourcexint.pdf](#) with indices of macros. Colon in `:=` now optional for `\xintdefvar` and `\xintdeffunc`.
- Release 1.3b of 2018/05/18: randomness related additions (still WIP).
- Release 1.3a of 2018/03/07: efficiency fix of the mechanism for recursive functions.
- Release 1.3 of 2018/03/01: addition and subtraction use systematically least common multiple of denominators. Extensive under-the-hood refactoring of `\xintNewExpr` and `\xintdeffunc` which now allow recursive definitions. Removal of 1.2o deprecated macros.
- Release 1.2q of 2018/02/06: bugfix release (1.2l subtraction bug in special situation); tacit multiplication extended to cases such as `10!20!30!`.
- Release 1.2p of 2017/12/05: maps `//` and `/:` to the floored, not truncated, division. Simultaneous assignments possible with `\xintdefvar`. Efficiency improvements in [xinttools](#).
- Release 1.2o of 2017/08/29: massive deprecations of those macros from [xintcore](#) and [xint](#) which filtered their arguments via `\xintNum`.
- Release 1.2n of 2017/08/06: improvements of [xintbinhex](#).
- Release 1.2m of 2017/07/31: rewrite of [xintbinhex](#) in the style of the 1.2 techniques.
- Release 1.2l of 2017/07/26: under the hood efficiency improvements in the style of the 1.2 techniques; subtraction refactored. Compatibility of most [xintfrac](#) macros with arguments using non-delimited `\the\numexpr` or `\the\mathcode` etc...
- Release 1.2i of 2016/12/13: under the hood efficiency improvements in the style of the 1.2 techniques.
- Release 1.2 of 2015/10/10: complete refactoring of the core arithmetic macros and faster [\xintexpr](#) parser.

- Release 1.1 of 2014/10/28: extensive changes in [xintexpr](#). Addition and subtraction do not multiply denominators blindly but sometimes produce smaller ones. Also with that release, packages [xintkernel](#) and [xintcore](#) got extracted from [xinttools](#) and [xint](#).

Some parts of the code still date back to the initial release, and at that time I was learning my trade in expandable TeX macro programming. At some point in the future, I will have to re-examine the older parts of the code.

Warning: pay attention when looking at the code to the catcode configuration as found in `\XINT-setcatcodes`. Additional temporary configuration is used at some locations. For example `!` is of catcode letter in [xintexpr](#) and there are locations with funny catcodes e.g. using some letters with the math shift catcode.

2 Package [xintkernel](#) implementation

.1	Catcodes, ε -TeX and reload detection . . .	4	.10	<code>\xint_zapspace</code>	10
.1.1	<code>\XINT_setcatcodes</code> , <code>\XINT_storecatcodes</code> , <code>\XINT_restorecatcodes_endinput</code>	5	.11	<code>\odef</code> , <code>\oodef</code> , <code>\fdef</code>	10
.2	Package identification	7	.12	<code>\xintReverseOrder</code>	10
.3	Constants	7	.13	<code>\xintLength</code>	11
.4	(WIP) <code>\xint_texuniformdeviate</code> and needed counts	7	.14	<code>\xintLastItem</code>	11
.5	Token management utilities	8	.15	<code>\xintLengthUpTo</code>	12
.6	"gob til" macros and UD style fork	8	.16	<code>\xintreplicate</code>	13
.7	<code>\xint_afterfi</code>	9	.17	<code>\xintgobble</code>	14
.8	<code>\xint_bye</code> , <code>\xint_Bye</code>	9	.18	(WIP) <code>\xintUniformDeviat</code>	16
.9	<code>\xintdothis</code> , <code>\xintorthat</code>	9	.19	<code>\xintMessage</code> , <code>\ifxintverbose</code>	17
			.20	<code>\ifxintglobaldefs</code> , <code>\XINT_global</code>	17
			.21	(WIP) Expandable error message	17

This package provides the common minimal code base for loading management and catcode control and also a few programming utilities. With 1.2 a few more helper macros and all `\chardef`'s have been moved here. The package is loaded by both `xintcore.sty` and `xinttools.sty` hence by all other packages.

1.1. separated package.

1.2i. `\xintreplicate`, `\xintgobble`, `\xintLengthUpTo` and `\xintLastItem`, and faster `\xintLength`.

1.3b. `\xintUniformDeviat`.

2.1 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from $\text{\textcircled{H}}\text{\textcircled{E}}\text{\textcircled{I}}\text{\textcircled{K}}\text{\textcircled{O}}$ $\text{\textcircled{O}}\text{\textcircled{B}}\text{\textcircled{E}}\text{\textcircled{R}}\text{\textcircled{D}}\text{\textcircled{I}}\text{\textcircled{E}}\text{\textcircled{K}}$'s packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

```

2.2 Package identification

Inspired from HEIKO OBERDIEK's packages. Modified in 1.09b to allow re-use in the other modules. Also I assume now that if `\ProvidesPackage` exists it then does define `\ver@<pkgname>.sty`, code of HO for some reason escaping me (compatibility with LaTeX 2.09 or other things ??) seems to set extra precautions.

1.09c uses e-TeX `\ifdefined`.

```

123 \ifdefined\ProvidesPackage
124   \let\XINT_providespackage\relax
125 \else
126   \def\XINT_providespackage #1#2[#3]%
127     {\immediate\write-1{Package: #2 #3}%
128     \expandafter\xdef\csname ver@#2.sty\endcsname{#3}}%
129 \fi
130 \XINT_providespackage
131 \ProvidesPackage {xintkernel}%
132 [2019/09/10 v1.3f Paraphernalia for the xint packages (JFB)]%
```

2.3 Constants

```

```

2.10 `\xint_zapspaces`

1.1.

This little utility zaps leading, intermediate, trailing, spaces in completely expanding context (`\edef`, `\csname...\endcsname`).

Usage: `\xint_zapspaces foo<space>\xint_gobble_i`

Will remove some brace pairs (but not spaces inside them). By the way the `\zap@spaces` of LaTeX2e handles unexpectedly things such as

```
\zap@spaces 1 {22} 3 4 \@empty
```

(spaces are not all removed). This does not happen with `\xint_zapspaces`.

Explanation: if there are leading spaces, then the first #1 will be empty, and the first #2 being undelimited will be stripped from all the remaining leading spaces, if there was more than one to start with. Of course brace-stripping may occur. And this iterates: each time a #2 is removed, either we then have spaces and next #1 will be empty, or we have no spaces and #1 will end at the first space. Ultimately #2 will be `\xint_gobble_i`.

This is not really robust as it may switch the expansion order of macros, and the `\xint_zapspaces` token might end up being fetched up by a macro. But it is enough for our purposes, for example:

```
\the\numexpr\xint_zapspaces 1 2 \xint_gobble_i\relax
```

expands to `12`, not to `12\relax`.

1.2e. `\xint_zapspaces_o`. Expansion of #1 should not gobble a space!

1.2i. made `\long`.

```
241 \long\def\xint_zapspaces #1 #2{#1#2\xint_zapspaces }% 1.1
242 \long\def\xint_zapspaces_o #1{\expandafter\xint_zapspaces#1 \xint_gobble_i}%
```

2.11 `\odef`, `\oodef`, `\fdef`

May be prefixed with `\global`. No parameter text.

```

251 \ifdefined\fdef\else\let\fdef\xintfdef\fi
```

2.12 `\xintReverseOrder`

1.0. does not expand its argument. The whole of xint codebase now contains only two calls to `\XINT_rord_main` (in `xintgcd`).

Attention: removes brace pairs (and swallows spaces).

For digit tokens a faster reverse macro is provided by (1.2) `\xintReverseDigits` in `xint`.

For comma separated items, 1.2g has `\xintCSVReverse` in `xinttools`.

```
252 \def\xintReverseOrder {\romannumeral0\xintreverseorder }%
253 \long\def\xintreverseorder #1%

2.15 \xintLengthUpTo

1.2i. for use by [\xintKeep](#) and [\xintTrim](#) ([xinttools](#)). The argument N **must be non-negative**.

[\xintLengthUpTo{N}{List}](#) produces -0 if length(List)>N, else it returns N-length(List). Hence subtracting it from N always computes min(N,length(List)).

1.2j. changed ending and interface to core loop.

```

2.16 \xintreplicate

1.2i.

This is cloned from LaTeX3's `\prg_replicate:n`, see Joseph's post at

<http://tex.stackexchange.com/questions/16189/repeat-command-n-times>

I posted there an alternative not using the chained `\csname`'s but it is a bit less efficient (except perhaps for thousands of repetitions). The code in Joseph's post does `abs(#1)` replications when input `#1` is negative and then activates an error triggering macro; here we simply do nothing when `#1` is negative.

Usage: `\romannumeral\xintreplicate{N}{stuff}`

When `N` is already explicit digits (even `N=0`, but non-negative) one can call the macro as

`\romannumeral\XINT_rep N\endcsname {foo}`

to skip the `\numexpr`.

```

Release 1.09g of 2013/11/22 splits off `xinttools.sty` from `xint.sty`. Starting with 1.1, [xinttools](#) ceases being loaded automatically by `xint`.

3.1 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified. The method for catcodes was also initially directly inspired by these packages.

```

3.5 \xintZapFirstSpaces

1.09f, written [2013/11/01]. Modified (2014/10/21) for release 1.1 to correct the bug in case of an empty argument, or argument containing only spaces, which had been forgotten in first version. New version is simpler than the initial one. This macro does NOT expand its argument.

```

90 \def\xintZapFirstSpaces {\romannumeral0\xintzapfirstspaces }%
91 \def\xintzapfirstspaces#1{\long
92 \def\xintzapfirstspaces ##1{\XINT_zapbsp_a #1##1\xint:#1#1\xint:}%
93 }\xintzapfirstspaces{ }%

```

If the original #1 started with a space, the grabbed #1 is empty. Thus `_again?` will see `#1=\xint_bye`, and hand over control to `_again` which will loop back into `\XINT_zapbsp_a`, with one

initial space less. If the original #1 did not start with a space, or was empty, then the #1 below will be a <sptoken>, then an extract of the original #1, not empty and not starting with a space, which contains what was up to the first <sp><sp> present in original #1, or, if none preexisted, <sptoken> and all of #1 (possibly empty) plus an ending \xint:. The added initial space will stop later the \romannumeral0. No brace stripping is possible. Control is handed over to \XINT_zapbsp_b which strips out the ending \xint:<sp><sp>\xint:

```
94 \def\XINT_zapbsp_a#1{\long\def\XINT_zapbsp_a ##1#1#1{%
95 \XINT_zapbsp_again?##1\xint_bye\XINT_zapbsp_b ##1#1#1}%
96 }\XINT_zapbsp_a{ }%
97 \long\def\XINT_zapbsp_again? #1{\xint_bye #1\XINT_zapbsp_again }%
98 \xint_firstofone{\def\XINT_zapbsp_again\XINT_zapbsp_b} {\XINT_zapbsp_a }%
99 \long\def\XINT_zapbsp_b #1\xint:#2\xint:{#1}%
```

3.6 \xintZapLastSpaces

1.09f, written [2013/11/01].

```
100 \def\xintZapLastSpaces {\romannumeral0\xintzaplastspaces }%
101 \def\xintzaplastspaces#1{\long
102 \def\xintzaplastspaces ##1{\XINT_zapbsp_a {} \empty##1#1#1\xint_bye\xint:}%
103 }\xintzaplastspaces{ }%
```

The \empty from \xintzaplastspaces is to prevent brace removal in the #2 below. The \expandafter chain removes it.

```
104 \xint_firstofone {\long\def\XINT_zapbsp_a #1#2 } %<- second space here
105 { \expandafter\XINT_zapbsp_b\expandafter{#2}{#1}}%
```

Notice again an \empty added here. This is in preparation for possibly looping back to \XINT_zapbsp_a. If the initial #1 had no <sp><sp>, the stuff however will not loop, because #3 will already be <some spaces>\xint_bye. Notice that this macro fetches all way to the ending \xint:. This looks not very efficient, but how often do we have to strip ending spaces from something which also has inner stretches of _multiple_ space tokens ?;-).

```
106 \long\def\XINT_zapbsp_b #1#2#3\xint:%
107 { \XINT_zapbsp_end? #3\XINT_zapbsp_e {#2#1} \empty #3\xint:}%
```

When we have been over all possible <sp><sp> things, we reach the ending space tokens, and #3 will be a bunch of spaces (possibly none) followed by \xint_bye. So the #1 in _end? will be \xint_bye. In all other cases #1 can not be \xint_bye (assuming naturally this token does nor arise in original input), hence control falls back to \XINT_zapbsp_e which will loop back to \XINT_zapbsp_a.

```
108 \long\def\XINT_zapbsp_end? #1{\xint_bye #1\XINT_zapbsp_end }%
```

We are done. The #1 here has accumulated all the previous material, and is stripped of its ending spaces, if any.

```
109 \long\def\XINT_zapbsp_end\XINT_zapbsp_e #1#2\xint:{ #1}%
```

We haven't yet reached the end, so we need to re-inject two space tokens after what we have gotten so far. Then we loop.

```
110 \def\XINT_zapbsp_e#1{%
111 \long\def\XINT_zapbsp_e ##1{\XINT_zapbsp_a {##1#1#1}}%
112 }\XINT_zapbsp_e{ }%
```

3.7 \xintZapSpaces

1.09f, written [2013/11/01]. Modified for 1.1, 2014/10/21 as it has the same bug as \xintZapFirstSpaces. We in effect do first \xintZapFirstSpaces, then \xintZapLastSpaces.

```

```

3.9 \xintCSVtoList, \xintCSVtoListNonStripped

\xintCSVtoList transforms a,b,...,z into {a}{b}...{z}. The comma separated list may be a macro which is first f-expanded. First included in release 1.06. Here, use of \Z (and \R) perfectly safe.

[2013/11/02]: Starting with 1.09f, automatically filters items with \xintZapSpacesB to strip away all spaces around commas, and spaces at the start and end of the list. The original is kept as \xintCSVtoListNonStripped, and is faster. But ... it doesn't strip spaces.

ATTENTION: if the input is empty the output contains one item (empty, of course). This means an \xintFor loop always executes at least once the iteration, contrarily to \xintFor*.

```

3.10 \xintListWithSep

1.04. `\xintListWithSep {sep}{a}{b}...{z}` returns a `\sep b \sep ... \sep z`. It f-expands its second argument. The 'sep' may be `\par`'s: the macro `\xintlistwithsep` etc... are all declared long. 'sep' does not have to be a single token. It is not expanded. The "list" argument may be empty.

`\xintListWithSepNoExpand` does not f-expand its second argument.

This venerable macro from 1.04 remained unchanged for a long time and was finally refactored at 1.2p for increased speed. Tests done with a list of identical `{\x}` items and a sep of `\z` demonstrated a speed increase of about:

- 3x for 30 items,
- 4.5x for 100 items,
- 7.5x--8x for 1000 items.

```

3.11 \xintNthElt

First included in release 1.06. Last refactored in 1.2j.

`\xintNthElt {i}{List}` returns the *i* th item from List (one pair of braces removed). The list is first f-expanded. The `\xintNthEltNoExpand` does no expansion of its second argument. Both variants expand *i* inside `\numexpr`.

With *i* = 0, the number of items is returned using `\xintLength` but with the List argument f-expanded first.

Negative values return the |*i*|th element from the end.

When *i* is out of range, an empty value is returned.

```

3.12 \xintKeep

First included in release 1.09m.

`\xintKeep{i}{L}` f-expands its second argument L. It then grabs the first i items from L and discards the rest.

ATTENTION: **each such kept item is returned inside a brace pair** Use `\xintKeepUnbraced` to avoid that.

For i equal or larger to the number N of items in (expanded) L, the full L is returned (with braced items). For i=0, the macro returns an empty output. For i<0, the macro discards the first N-|i| items. No brace pairs added to the remaining items. For i is less or equal to -N, the full L is returned (with no braces added.)

`\xintKeepNoExpand` does not expand the L argument.

Prior to 1.2i the code proceeded along a loop with no pre-computation of the length of L, for the i>0 case. The faster 1.2i version takes advantage of novel `\xintLengthUpTo` from `xintkernel.sty`.

3.13 \xintKeepUnbraced

1.2a. Same as `\xintKeep` but will *not* add (or maintain) brace pairs around the kept items when `length(L)>i>0`.

The name may cause a mis-understanding: for `i<0`, (i.e. keeping only trailing items), there is no brace removal at all happening.

Modified for 1.2i like `\xintKeep`.

3.14 `\xintTrim`

First included in release 1.09m.

`\xintTrim{i}{L}` f-expands its second argument L. It then removes the first i items from L and keeps the rest. For i equal or larger to the number N of items in (expanded) L, the macro returns an empty output. For i=0, the original (expanded) L is returned. For i<0, the macro proceeds from the tail. It thus removes the last |i| items, i.e. it keeps the first N-|i| items. For |i|>= N, the empty list is returned.

`\xintTrimNoExpand` does not expand the L argument.

Speed improvements with 1.2i for i<0 branch (which hands over to `\xintKeep`). Speed improvements with 1.2j for i>0 branch which gobbles items nine by nine despite not knowing in advance if it will go too far.

3.16 \xintApply

`\xintApply` `{\macro}{a}{b}...{z}` returns `{\macro{a}}...{\macro{b}}` where each instance of `\macro` is f-expanded. The list itself is first f-expanded and may thus be a macro. Introduced with release 1.04.

```

```

3.17 \xintApplyUnbraced

`\xintApplyUnbraced` `{\macro}{a}{b}...{z}` returns `\macro{a}...{\macro{z}}` where each instance of `\macro` is f-expanded using `\romannumeral-`0`. The second argument may be a macro as it is itself also f-expanded. No braces are added: this allows for example a non-expandable `\def` in `\macro`, without having to do `\gdef`. Introduced with release 1.06b.

```

3.22 `\xintApplyInline`

1.09a: `\xintApplyInline\macro{{a}{b}...{z}}` has the same effect as executing `\macro{a}` and then applying again `\xintApplyInline` to the shortened list `{{b}...{z}}` until nothing is left. This is a non-expandable command which will result in quicker code than using `\xintApplyUnbraced`. It f-expands its second (list) argument first, which may thus be encapsulated in a macro.

Rewritten in 1.09c. Nota bene: uses catcode 3 Z as privated list terminator.

```

3.23 `\xintFor`, `\xintFor*`, `\xintBreakFor`, `\xintBreakForAndDo`

1.09c [2013/10/09]: a new kind of loop which uses macro parameters #1, #2, #3, #4 rather than macros; while not expandable it survives executing code closing groups, like what happens in an alignment with the & character. When inserted in a macro for later use, the # character must be doubled.

The non-star variant works on a csv list, which it expands once, the star variant works on a token list, which it (repeatedly) f-expands.

1.09e adds `\XINT_forever` with `\xintintegers`, `\xintdimensions`, `\xintrationals` and `\xintBreakFor`, `\xintBreakForAndDo`, `\xintifForFirst`, `\xintifForLast`. On this occasion `\xint_firstoftwo` and `\xint_secondoftwo` are made long.

1.09f: rewrites large parts of `\xintFor` code in order to filter the comma separated list via `\xintCSVtoList` which gets rid of spaces. The `#1` in `\XINT_for_forever?` has an initial space token which serves two purposes: preventing brace stripping, and stopping the expansion made by `\xintcsvtolist`. If the `\XINT_forever` branch is taken, the added space will not be a problem there.

1.09f rewrites (2013/11/03) the code which now allows all macro parameters from `#1` to `#9` in `\xintFor`, `\xintFor*`, and `\XINT_forever`. 1.2i: slightly more robust `\xintifForFirst/Last` in case of nesting.

3.24 \XINT_forever, \xintintegers, \xintdimensions, \xintrationals

New with 1.09e. But this used inadvertently \xintiadd/\xintimul which have the unnecessary \xintnum overhead. Changed in 1.09f to use \xintiiadd/\xintiimul which do not have this overhead. Also 1.09f uses \xintZapSpacesB for the \xintrationals case to get rid of leading and ending spaces in the #4 and #5 delimited parameters of \XINT_forever_opt_a (for \xintintegers and \xintdimensions this is not necessary, due to the use of \numexpr resp. \dimexpr in \XINT_?expr_Ua, resp. \XINT_?expr_Da).

3.25 \xintForpair, \xintForthree, \xintForfour

1.09c.

[2013/11/02] 1.09f \xintForpair delegate to \xintCSVtoList and its \xintZapSpacesB the handling of spaces. Does not share code with \xintFor anymore.

[2013/11/03] 1.09f: \xintForpair extended to accept #1#2, #2#3 etc... up to #8#9, \xintForthree, #1#2#3 up to #7#8#9, \xintForfour id.

1.2i: slightly more robust \xintifForFirst/Last in case of nesting.

3.26 \xintAssign, \xintAssignArray, \xintDigitsOf

`\xintAssign {a}{b}..{z}\to\A\B...Z` resp. `\xintAssignArray {a}{b}..{z}\to\U`.

`\xintDigitsOf=\xintAssignArray`.

1.1c 2015/09/12 has (belatedly) corrected some "features" of `\xintAssign` which didn't like the case of a space right before the `"\to"`, or the case with the first token not an opening brace and the subsequent material containing brace groups. The new code handles gracefully these situations.

```

3.28 CSV (non user documented) variants of Length, Keep, Trim, NthElt, Reverse

These routines are for use by `\xintListSel:x:csv` and `\xintListSel:f:csv` from `xintexpr`, and also for the `reversed` and `len` functions. Refactored for 1.2j release, following 1.2i updates to `\xintKeep`, `\xintTrim`, ...

These macros will remain undocumented in the user manual:

-- they exist primarily for internal use by the `xintexpr` parsers, hence don't have to be general purpose; for example, they a priori need to handle only catcode 12 tokens (not true in `\xintNewExpr`, though) hence they are not really worried about controlling brace stripping (nevertheless 1.2j has paid some secondary attention to it, see below.) They are not worried about normalizing leading spaces either, because none will be encountered when the macros are used as auxiliaries to the expression parsers.

-- crucial design elements may change in future:

1. whether the handled lists must have or not have a final comma. Currently, the model is the one of comma separated lists with **no** final comma. But this means that there can not be a distinction of principle between a truly empty list and a list which contains one item which turns out to be empty. More importantly it makes the coding more complicated as it is needed to distinguish the empty list from the single-item list, both lacking commas.

For the internal use of `xintexpr`, it would be ok to require all list items to be terminated by a comma, and this would bring quite some simplifications here, but as initially I started with non-terminated lists, I have left it this way in the 1.2j refactoring.

2. the way to represent the empty list. I was tempted for matter of optimization and synchronization with `xintexpr` context to require the empty list to be always represented by a space token and to not let the macros admit a completely empty input. But there were complications so for the time being 1.2j does accept truly empty output (it is not distinguished from an input equal to a space token) and produces empty output for empty list. This means that the status of the «nil» object for the `xintexpr` parsers is not completely clarified (currently it is represented by a space token).

The original Python slicing code in `xintexpr` 1.1 used `\xintCSVtoList` and `\xintListWithSep{,}` to convert back and forth to token lists and apply `\xintKeep/\xintTrim`. Release 1.2g switched to devoted f-expandable macros added to [xinttools](#). Release 1.2j refactored all these macros as a follow-up to 1.2i improvements to `\xintKeep/\xintTrim`. They were made `\long` on this occasion and auxiliary `\xintLengthUpTo:f:csv` was added.

Leading spaces in items are currently maintained as is by the 1.2j macros, even by `\xintNthEltPy:f:csv`, with the exception of the first item, as the list is f-expanded. Perhaps `\xintNthEltPy:f:csv` should remove a leading space if present in the picked item; anyway, there are no spaces for the lists handled internally by the Python slicer of `xintexpr`, except the «nil» object currently represented by exactly one space.

Kept items (with no leading spaces; but first item special as it will have lost a leading space due to f-expansion) will lose a brace pair under `\xintKeep:f:csv` if the first argument was positive and strictly less than the length of the list. This differs of course from `\xintKeep` (which always braces items it outputs when used with positive first argument) and also from `\xintKeepUnbraced` in the case when the whole list is kept. Actually the case of singleton list is special, and brace removal will happen then.

This behaviour was otherwise for releases earlier than 1.2j and may change again.

Directly usable names are provided, but these macros (and the behaviour as described above) are to be considered *unstable* for the time being.

3.28.1 `\xintLength:f:csv`

1.2g. Redone for 1.2j. Contrarily to `\xintLength` from `xintkernel.sty`, this one expands its argument.

```
1126 \def\xintLength:f:csv {\romannumeral0\xintlength:f:csv}%
1127 \def\xintlength:f:csv #1%
1128 {\long\def\xintlength:f:csv ##1{%

3.28.3 \xintKeep:f:csv

1.2g 2016/03/17. Redone for 1.2j with use of \xintLengthUpTo:f:csv. Same code skeleton as \xintKeep but handling comma separated but non terminated lists has complications. The \xintKeep in case of a negative #1 uses \xintgobble, we don't have that for comma delimited items, hence we do a special loop here (this style of loop is surely competitive with xintgobble for a few dozens items and even more). The loop knows before starting that it will not go too far.

```

This strange thing is in case the picked item was the last one, hence there was an ending `\xint:` (we could not put a comma earlier for matters of not confusing empty list with a singleton list), and we do this here to activate brace-stripping of item as all other items may be brace-stripped if picked. This is done for coherence. Of course, in the context of the `xintexpr.sty` parsers, there are no braces in list items...

```

3.28.7 `\xintFirstItem:f:csv`

Added with 1.2k for use by `first()` in `\xintexpr`-essions, and some amount of compatibility with `\xintNewExpr`.

```
1424 \def\xintFirstItem:f:csv {\romannumeral0\xintfirstitem:f:csv}%
1425 \long\def\xintfirstitem:f:csv #1%
1426 {%
1427   \expandafter\XINT_first:f:csv_a\romannumeral`&&#1,\xint_bye
1428 }%
1429 \long\def\XINT_first:f:csv_a #1,#2\xint_bye{ #1}%
```

3.28.8 `\xintLastItem:f:csv`

Added with 1.2k, based on and sharing code with `xintkernel`'s `\xintLastItem` from 1.2i. Output empty if input empty. `f`-expands its argument (hence first item, if not protected.) For use by `last()` in `\xintexpr`-essions with to some extent `\xintNewExpr` compatibility.

```

1430 \def\xintLastItem:f:csv {\romannumeral0\xintlastitem:f:csv}%
1431 \long\def\xintlastitem:f:csv #1%

```

3.28.9 Public names for the undocumented csv macros: `\xintCSVLength`, `\xintCSVKeep`, `\xintCSVTrim`, `\xintCSVNthEltPy`, `\xintCSVReverse`, `\xintCSVFirstItem`, `\xintCSVLastItem`

Completely unstable macros: currently they expand the list argument and want no final comma. But for matters of `xintexpr.sty` I could as well decide to require a final comma, and then I could simplify implementation but of course this would break the macros if used with current functionalities.

```

1446 \let\xintCSVLength   \xintLength:f:csv
1447 \let\xintCSVKeep     \xintKeep:f:csv
1448 \let\xintCSVTrim     \xintTrim:f:csv

Got split off from [xint](#) with release 1.1.

The core arithmetic routines have been entirely rewritten for release 1.2. The 1.2i and 1.2j brought again some improvements.

The commenting continues (2019/09/10) to be very sparse: actually it got worse than ever with release 1.2. I will possibly add comments at a later date, but for the time being the new routines are not commented at all.

1.3 removes all macros which were deprecated at 1.2o.

4.1 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from ΗΕΙΚΟ ΟΒΕΡΔΙΕΚ's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

4.3 (WIP!) Error conditions and exceptions

As per the Mike Cowlishaw/IBM's General Decimal Arithmetic Specification

<http://speleotrove.com/decimal/decarith.html>

and the Python3 implementation in its Decimal module.

Clamped, ConversionSyntax, DivisionByZero, DivisionImpossible, DivisionUndefined, Inexact, InsufficientStorage, InvalidContext, InvalidOperation, Overflow, Inexact, Rounded, Subnormal, Underflow.

X3.274 rajoute LostDigits

Python rajoute FloatOperation (et n'inclut pas InsufficientStorage)

quote de decarith.pdf: The Clamped, Inexact, Rounded, and Subnormal conditions can coincide with each other or with other conditions. In these cases then any trap enabled for another condition takes precedence over (is handled before) all of these, any Subnormal trap takes precedence over Inexact, any Inexact trap takes precedence over Rounded, and any Rounded trap takes precedence over Clamped.

WORK IN PROGRESS ! (1.21, 2017/07/26)

I follow the Python terminology: a trapped signal means it raises an exception which for us means an expandable error message with some possible user interaction. In this WIP state, the interaction is commented out. A non-trapped signal or condition would activate a (presumably silent) handler.

Here, no signal-raising condition is "ignored" and all are "trapped" which means that error handlers are never activated, thus left in garbage state in the code.

Various conditions can raise the same signal.

Only signals, not conditions, raise Flags.

If a signal is ignored it does not raise a Flag, but it activates the signal handler (by default now no signal is ignored.)

If a signal is not ignored it raises a Flag and then if it is not trapped it activates the handler of the `_condition_`.

If trapped (which is default now) an «exception» is raised, which means an expandable error message (I copied over the LaTeX3 code for expandable error messages, basically) interrupts the TeX run. In future, user input could be solicited, but currently this is commented out.

For now macros to reset flags are done but without public interface nor documentation.

Only four conditions are currently possibly encountered:

- InvalidOperation
- DivisionByZero
- DivisionUndefined (which signals InvalidOperation)
- Underflow

I did it quickly, anyhow this will become more palpable when some of the Decimal Specification is actually implemented. The plan is to first do the X3.274 norm, then more complete implementation will follow... perhaps...

```

Routines handling integers as lists of token digits

Routines handling big integers which are lists of digit tokens with no special additional structure.

Some routines do not accept non properly terminated inputs like "\the\numexpr1", or "\the\mathcode\-\-", others do.

These routines or their sub-routines are mainly for internal usage.

4.5 \XINT_cuz_small

\XINT_cuz_small removes leading zeroes from the first eight digits. Expands following \romannumeral0. At least one digit is produced.

```

127 \def\XINT_cuz_small#1{%
128 \def\XINT_cuz_small ##1##2##3##4##5##6##7##8%
129 {%
130 \expandafter#1\the\numexpr ##1##2##3##4##5##6##7##8\relax
131 }}\XINT_cuz_small{ }%

```

4.6 \xintNum, \xintiNum

For example \xintNum {----+----+----000000000000003}

Very old routine got completely rewritten at 1.21.

New code uses \numexpr governed expansion and fixes some issues of former version particularly regarding inputs of the \numexpr...\relax type without \the or \number prefix, and/or possibly no terminating \relax.

\xintiNum{\numexpr 1}\foo in earlier versions caused premature expansion of \foo.

\xintiNum{\the\numexpr 1} was ok, but a bit luckily so.

Also, up to 1.2k inclusive, the macro fetched tokens eight by eight, and not nine by nine as is done now. I have no idea why.

\xintNum gets redefined by [xintfrac](#).

```

132 \def\xintiNum {\romannumeral0\xintinum }%
133 \def\xintinum #1%
134 {%
135 \expandafter\XINT_num_cleanup\the\numexpr\expandafter\XINT_num_loop
136 \romannumeral`&&@#1\xint:\xint:\xint:\xint:\xint:\xint:\xint:\xint:\xint:\Z
137 }%
138 \def\xintNum {\romannumeral0\xintnum }%
139 \let\xintnum\xintinum
140 \def\XINT_num #1%
141 {%
142 \expandafter\XINT_num_cleanup\the\numexpr\XINT_num_loop
143 #1\xint:\xint:\xint:\xint:\xint:\xint:\xint:\xint:\xint:\Z
144 }%
145 \def\XINT_num_loop #1#2#3#4#5#6#7#8#9%
146 {%

```

```

147 \xint_gob_til_xint: #9\XINT_num_end\xint:
148 #1#2#3#4#5#6#7#8#9%
149 \ifnum \numexpr #1#2#3#4#5#6#7#8#9+\xint_c_ = \xint_c_

```

means that so far only signs encountered, (if syntax is legal) then possibly zeroes or a terminated or not terminated `\numexpr` evaluating to zero In that latter case a correct zero will be produced in the end.

```

150 \expandafter\XINT_num_loop
151 \else

```

non terminated `\numexpr` (with nine tokens total) are safe as after `\fi`, there is then `\xint:`

```

152 \expandafter\relax
153 \fi
154 }%
155 \def\XINT_num_end\xint:#1\xint:{#1+\xint_c_\xint:}% empty input ok
156 \def\XINT_num_cleanup #1\xint:#2\Z { #1}%

```

4.7 `\xintiiSgn`

1.2l made `\xintiiSgn` robust against non terminated input.

1.2o deprecates here `\xintSgn` (it requires `xintfrac.sty`).

```

157 \def\xintiiSgn {\romannumeral0\xintiiSgn }%

Blocks of eight digits

The lingua of release 1.2.

4.19 \XINT_cuz

This (launched by `\romannumeral0`) iterately removes all leading zeroes from a sequence of 8N digits ended by `\R`.

Rewritten for 1.2l, now uses `\numexpr` governed expansion and `\ifnum` test rather than delimited gobbling macros.

Note 2015/11/28: with only four digits the gob_til_fourzeroes had proved in some old testing faster than \ifnum test. But with eight digits, the execution times are much closer, as I tested back then.

```

389 \def\XINT_cuz_byviii_e\R #1\XINT_cuz_byviii_done #2\R{ #2}%

```

4.21 \XINT_unsep_loop

This is used as

```

\the\numexpr0\XINT_unsep_loop (blocks of 1<8digits>!)
\xint_bye!2!3!4!5!6!7!8!9!\xint_bye\xint_c_i\relax

```

It removes the 1's and !'s, and outputs the 8N digits with a 0 token as as prefix which will have to be cleaned out by caller.

Actually it does not matter whether the blocks contain really 8 digits, all that matters is that they have 1 as first digit (and at most 9 digits after that to obey the TeX-\numexpr bound).

Done at 1.21 for usage by other macros. The similar code in earlier releases was strangely in $O(N^2)$ style, apparently to avoid some memory constraints. But these memory constraints related to \numexpr chaining seems to be in many places in xint code base. The 1.21 version is written in the 1.2i style of \xintInc etc... and is compatible with some 1! block without digits among the treated blocks, they will disappear.

```

390 \def\XINT_unsep_loop #1!#2!#3!#4!#5!#6!#7!#8!#9!%
391 {%
392     \expandafter\XINT_unsep_clean

530 }%

```

Core arithmetic

The four operations have been rewritten entirely for release 1.2. The new routines works with separated blocks of eight digits. They all measure first the lengths of the arguments, even addition and subtraction (this was not the case with xintcore.sty 1.1 or earlier.)

The technique of chaining `\the\numexpr` induces a limitation on the maximal size depending on the size of the input save stack and the maximum expansion depth. For the current (TL2015) settings (5000, resp. 10000), the induced limit for addition of numbers is at 19968 and for multiplication it is observed to be 19959 (valid as of 2015/10/07).

Side remark: I tested that `\the\numexpr` was more efficient than `\number`. But it reduced the allowable numbers for addition from 19976 digits to 19968 digits.

4.33 `\xintiiAdd`

1.21: `\xintiiAdd` made robust against non terminated input.

2 as first token of #1 stands for "no carry", 3 will mean a carry (we are adding 1<8digits> to 1<8digits>.) Version 1.2c has terminators of the shape 1;!, replacing the \Z! used in 1.2.

Call: \the\numexpr\XINT_add_a 2#11;!1;!1;!1;!1\W #21;!1;!1;!1;!1\W where #1 and #2 are blocks of 1<8d>!, and #1 is at most as long as #2. This last requirement is a bit annoying (if one wants to do recursive algorithms but not have to check lengths), and I will probably remove it at some point.

Output: blocks of 1<8d>! representing the addition, (least significant first), and a final 1;!.
In recursive algorithm this 1;! terminator can thus conveniently be reused as part of input terminator (up to the length problem).

4.35 \xintiiSub

Entirely rewritten for 1.2.

Refactored at 1.2l. I was initially aiming at clinching some internal format of the type `1<8digits>!...!<8digits>!` for chaining the arithmetic operations (as a preliminary step to deciding upon some internal format for `xintfrac` macros), thus I wanted to uniformize delimiters in particular and have some core macros inputting and outputting such formats. But the way division is implemented makes it currently very hard to obtain a satisfactory solution. For subtraction I got there almost, but there was added overhead and, as the core sub-routine still assumed the shorter number will be positioned first, one would need to record the length also in the basic internal format, or add the overhead to not make assumption on which one is shorter. I thus but back-tracked my steps but in passing I improved the efficiency (probably) in the worst case branch.

Sadly this 1.2l refactoring left an extra `!` in macro `\XINT_sub_l_Ida`. This bug shows only in rare circumstances which escaped out test suite :(Fixed at 1.2q.

The other reason for backtracking was in relation with the decimal numbers. Having a core format in base 10^8 but ultimately the radix is actually 10 leads to complications. I could use radix 10^8 for `\xintiiexpr` only, but then I need to make it compatible with sub-`\xintiiexpr` in `\xintexpr`, etc... there are many issues of this type.

I considered also an approach like in the 1.2l `\xintiiCmp`, but decided to stick with the method here for now.

The post-processing (clean-up of zeros, or rescue of situation with A-B where actually B turns out bigger than A) will be done by a macro which depends on circumstances and will be initially last token before the reversion done by `\XINT_unrevbyviii`.

```
848 \def\XINT_sub_out {\XINT_unrevbyviii{}}%
```

1 as first token of #1 stands for "no carry", 0 will mean a carry.

Call: `\the\numexpr`

```

\XINT_sub_a #1#1;!1;!1;!1;!1\W
          #2#1;!1;!1;!1;!1\W

```

where #1 and #2 are blocks of `1<8d>!`, #1 (=B) *must* be at most as long as #2 (=A), (in radix 10^8) and the routine wants to compute $\#2-\#1 = A - B$

1.2l uses `;!` delimiters to match those of addition (and multiplication). But in the end I reverted the code branch which made it possible to chain such operations keeping internal format in 8 digits blocks throughout.

`\numexpr` governed expansion stops with various possibilities:

- Type Ia: #1 shorter than #2, no final carry
- Type Ib: #1 shorter than #2, a final carry but next block of #2 > 1
- Type Ica: #1 shorter than #2, a final carry, next block of #2 is final and = 1
- Type Icb: as Ica except that 00000001 block from #2 was not final
- Type Id: #1 shorter than #2, a final carry, next block of #2 = 0
- Type IIa: #1 same length as #2, turns out it was \leq #2.
- Type IIb: #1 same length as #2, but turned out > #2.

Various type of post actions are then needed:

- Ia: clean up of zeros in most significant block of 8 digits
- Ib: as Ia
- Ic: there may be significant blocks of 8 zeros to clean up from result. Only case Ica may have arbitrarily many of them, case Icb has only one such block.
- Id: blocks of 99999999 may propagate and there might a be final zero block created which has to be cleaned up.
- IIa: arbitrarily many zeros might have to be removed.
- IIb: We wanted $\#2-\#1 = -(\#1-\#2)$, but we got $10^{\{8N\}}+\#2-\#1 = 10^{\{8N\}}-(\#1-\#2)$. We need to do the correction then we are as in IIa situation, except that final result can not be zero.

The 1.2l method for this correction is (presumably, testing takes lots of time, which I do not have) more efficient than in 1.2 release.

```

849 \def\XINT_sub_a #1!#2!#3!#4!#5\W #6!#7!#8!#9!%
850 {%
851 \XINT_sub_b

854 }%

```

As 1.2l code uses `1<8digits>!` blocks one has to be careful with the carry digit 1 or 0: A `#1#2#3` pattern would result into an empty #1 if the carry digit which is upfront is 1, rather than setting `#1=1`.

B terminated. Have we reached the end of A (necessarily at least as long as B) ? (we are computing A-B, digits of B come first).

If not, then we are certain that even if there is carry it will not propagate beyond the end of A. But it may propagate far transforming chains of 00000000 into 99999999, and if it does go to the final block which possibly is just $1 < 00000001 >!$, we will have those eight zeros to clean up.

If A and B have the same length (in base 10^8) then arbitrarily many zeros might have to be cleaned up, and if $A < B$, the whole result will have to be complemented first.

```

This is the case where both operands have same 10^8 -base length.

We were handling $A < B$ but perhaps $B > A$. The situation with $A = B$ is also annoying because we then have to clean up all zeros but don't know where to stop (if $A > B$ the first non-zero 8 digits block would tell use when).

Here again we need to grab $\#3\W$ to position the actually used terminating delimiters.

```

Call:

```
\the\numexpr \xINT_mul_loop 100000000!1;!W #11;!W #21;!
```

where #1 and #2 are (globally reversed) blocks $1 < 8d >$!. Its is generally more efficient if #1 is the shorter one, but a better recipe is implemented in `\XINT_mul_checklengths`. One may call `\XINT_mul_loop` directly (but multiplication by zero will produce many 100000000! blocks on output).

Ends after having produced: $1\langle 8d\rangle!\dots 1\langle 8d\rangle!1;!.$ The last 8-digits block is significant one. It can not be 100000000! except if the loop was called with a zero operand.

Thus `\XINT_mul_loop` can be conveniently called directly in recursive routines, as the output terminator can serve as input terminator, we can arrange to not have to grab the whole thing again.

```

```

1.2 small and mini multiplication in base 10^8 with carry. Used by the main multiplication routines. But division, float factorial, etc.. have their own variants as they need output with specific constraints.

The `minimulwc` has $1\langle 8\text{digits carry}\rangle.\langle 4\text{ high digits}\rangle.\langle 4\text{ low digits}\rangle\langle 8\text{digits}\rangle.$

It produces a block $1\langle 8d\rangle!$ and then jump back into `\XINT_smallmul_a` with the new 8digits carry as argument. The `\XINT_smallmul_a` fetches a new $1\langle 8d\rangle!$ block to multiply, and calls back `\XINT_minimul_wc` having stored the multiplicand for re-use later. When the loop terminates, the final carry is checked for being nul, and in all cases the output is terminated by a 1;!

Multiplication by zero will produce blocks of zeros.

4.37 \xintiiDivision

Completely rewritten for 1.2.

WARNING: some comments below try to describe the flow of tokens but they date back to xint 1.09j and I updated them on the fly while doing the 1.2 version. As the routine now works in base 10⁸,

not 10^4 and "drops" the quotient digits, rather than store them upfront as the earlier code, I may well have not correctly converted all such comments. At the last minute some previously #1 became stuff like #1#2#3#4, then of course the old comments describing what the macro parameters stand for are necessarily wrong.

Side remark: the way tokens are grouped was not essentially modified in 1.2, although the situation has changed. It was fine-tuned in xint 1.0/1.1 but the context has changed, and perhaps I should revisit this. As a corollary to the fact that quotient digits are now left behind thanks to the chains of \numexpr, some macros which in 1.0/1.1 fetched up to 9 parameters now need handle less such parameters. Thus, some rationale for the way the code was structured has disappeared.

1.21: \xintiDivision et al. made robust against non terminated input.

#1 = A, #2 = B. On calcule le quotient et le reste dans la division euclidienne de A par B: $A=BQ+R$, $0 \leq R < |B|$.

Donc attention malgré son nom \XINT_div_prepare va jusqu'au bout. C'est donc en fait l'entrée principale (pour $B > 0$, $A > 0$) mais elle va regarder si B est $< 10^8$ et s'il vaut alors 1 ou 2, et si $A < 10^8$. Dans tous les cas le résultat est produit sous la forme $\{Q\}\{R\}$, avec Q et R sous leur forme final. On doit ensuite ajuster si le B ou le A initial était négatif. Je n'ai pas fait beaucoup d'efforts pour être un minimum efficace si A ou B n'est pas positif.

```

Special very small multiplication for division. We only need to cater for multiplicands from 1 to 9. The ending is different from standard `verysmallmul`, a zero carry is not suppressed. And no final `1;!` is added. If multiplicand is just 1 let's not forget to add the zero carry `10000000!` at the end.

```

Ici $B < 10^8$ (et est > 2). On exécute `\expandafter\XINT_sdiv_out\the\numexpr\XINT_smalldivx_a x.1B!1<8d>!\dots1<8d>!1;!` avec $x = \text{round}(B/2)$, $1B = 10^8 + B$, et A déjà en blocs `1<8d>!` (non renversés). Le `\the\numexpr\XINT_smalldivx_a` va produire `Q\Z R\W` avec un $R < 10^8$, et un Q sous forme de blocs `1<8d>!` terminé par `1!` et nécessitant le nettoyage du premier bloc. Dans cette branche le B n'a pas été multiplié par une puissance de 10, il peut avoir moins de huit chiffres.

```

1640 \def\XINT_sdiv_out #1;!#2!%

Cette routine fait la division euclidienne d'un nombre de seize chiffres par $\#1 = C =$ diviseur sur huit chiffres $\geq 10^7$, avec $\#2 =$ sa moitié utilisée dans `\numexpr` pour contrebalancer l'arrondi (ARRRRRRGGGGHHHH) fait par `/`. Le nombre divisé $XY = X \cdot 10^8 + Y$ se présente sous la forme `1<8chiffres>!1<8chiffres>!` avec plus significatif en premier.

Seul le quotient est calculé, pas le reste. En effet la routine de division principale va utiliser ce quotient pour déterminer le "grand" reste, et le petit reste ici ne nous serait d'à peu près aucune utilité.

ATTENTION UNIQUEMENT UTILISÉ POUR DES SITUATIONS OÙ IL EST GARANTI QUE $X < C$! (et C au moins 10^7) le quotient euclidien de $X \cdot 10^8 + Y$ par C sera donc $< 10^8$. Il sera renvoyé sous la forme `1<8chiffres>`.

4.46 \xintiiPow

The exponent is not limited but with current default settings of tex memory, with xint 1.2, the maximal exponent for 2^N is $N = 2^{17} = 131072$.

1.2f Modifies the initial steps: 1) in order to be able to let more easily \xintiPow use \xintNum on the exponent once xintfrac.sty is loaded; 2) also because I noticed it was not very well coded. And it did only a \numexpr on the exponent, contradicting the documentation related to the "i" convention in names.

1.2l: \xintiiPow made robust against non terminated input.

4.47 `\xintiFac`

Moved here from `xint.sty` with release 1.2 (to be usable by `\bnumexpr`).

An `\xintiFac` is needed by `xintexpr.sty`. Prior to 1.2o it was defined here as an alias to `\xintiFac`, then redefined by `xintfrac` to use `\xintNum`. This was incoherent. Contrarily to other similarly named macros, `\xintiFac` uses `\numexpr` on its input. This is also incoherent with the naming scheme, alas.

Partially rewritten with release 1.2 to benefit from the inner format of the 1.2 multiplication.

With current default settings of the `etex` memory and `a.t.t.o.w` (11/2015) the maximal possible computation is $5971!$ (which has 19956 digits).

Note (end november 2015): I also tried out a quickly written recursive (binary split) implementation

```

and I was quite surprised that it was only about $1.6x$ -- $2x$ slower in the range $N=200$ to 2000 than the `\xintiifac` here which attempts to be smarter...

Note (2017, 1.21): I found out some code comment of mine that the code here should be more in the style of `\xintiiBinomial`, but I left matters untouched.

1.2o modifies `\xintiifac` to be coherent with `\xintiiBinomial`: only with `xintfrac.sty` loaded does it use `\xintNum`. It is documented only as macro of `xintfrac.sty`, not as macro of `xint.sty`.

--	---

With release 1.1 the core arithmetic routines `\xintiiAdd`, `\xintiiSub`, `\xintiiMul`, `\xintiiQuo`, `\xintiiPow` were separated to be the main component of the then new *xintcore*.

At 1.3 the macros deprecated at 1.2o got all removed.

1.3b adds randomness related macros.

57   \fi
58 \fi

```

5.4 `\xintLen`, `\xintiLen`

`\xintLen` gets extended to fractions by `xintfrac.sty`: A/B is given length $\text{len}(A)+\text{len}(B)-1$ (somewhat arbitrary). It applies `\xintNum` to its argument. A minus sign is accepted and ignored.

For parallelism with `\xintiNum`/`\xintNum`, 1.2o defines `\xintilen`.

`\xintLen` gets redefined by `xintfrac`.

```

84   \expandafter\XINT_length_loop\xint_UDsignfork#1{-#1\krof}%

```

5.6 `\xintReverseDigits`

1.2.

This puts digits in reverse order, not suppressing leading zeros after reverse. Despite lacking the "ii" in its name, it does not apply `\xintNum` to its argument (contrarily to `\xintLen`, this is not very coherent).

1.2l variant is robust against non terminated `\the\numexpr` input.

This macro is currently not used elsewhere in `xint` code.

5.7 \xintiiE

Originally was used in `\xintiexpr`. Transferred from `xintfrac` for 1.1. Code rewritten for 1.2i. `\xintiiE{x}{e}` extends x with e zeroes if e is positive and simply outputs x if e is zero or negative. Attention, le comportement pour $e < 0$ ne doit pas être modifié car `\xintMod` et autres macros en dépendent.

```

134 \def\XINT_ii_neg #1.#2;{ #2}%
```

5.8 \xintDecSplit

DECIMAL SPLIT

The macro `\xintDecSplit {x}{A}` cuts A which is composed of digits (leading zeroes ok, but no sign) (*) into two (each possibly empty) pieces L and R. The concatenation LR always reproduces A.

The position of the cut is specified by the first argument x. If x is zero or positive the cut location is x slots to the left of the right end of the number. If x becomes equal to or larger than the length of the number then L becomes empty. If x is negative the location of the cut is |x| slots to the right of the left end of the number.

(*) versions earlier than 1.2i first replaced A with its absolute value. This is not the case anymore. This macro should NOT be used for A with a leading sign (+ or -).

Entirely rewritten for 1.2i (2016/12/11).

Attention: `\xintDecSplit` not robust against non terminated second argument.

5.13 \xintDSx

--> Attention le cas $x=0$ est traité dans la même catégorie que $x > 0$ <--

si $x < 0$, fait $A \rightarrow A \cdot 10^{|x|}$

si $x \geq 0$, et $A \geq 0$, fait $A \rightarrow \{ \text{quo}(A, 10^x) \} \{ \text{rem}(A, 10^x) \}$

si $x \geq 0$, et $A < 0$, d'abord on calcule $\{ \text{quo}(-A, 10^x) \} \{ \text{rem}(-A, 10^x) \}$

puis, si le premier n'est pas nul on lui donne le signe -

si le premier est nul on donne le signe - au second.

On peut donc toujours reconstituer l'original A par $10^x Q \pm R$ où il faut prendre le signe plus si Q est positif ou nul et le signe moins si Q est strictement négatif.

Rewritten for 1.2i, this was old code.

510 }%
```

5.38 `\xintifTrueAelseB`, `\xintifFalseAelseB`

1.09i. 1.2i has removed deprecated `\xintifTrueFalse`, `\xintifTrue`.

1.2o uses `\xintiiifNotZero`, see comments to `\xintAND` etc... This will work fine with arguments being nested `xintfrac.sty` macros, without the overhead of `\xintNum` or `\xintRaw` parsing.

```
511 \def\xintifTrueAelseB {\romannumeral0\xintiiifnotzero}%
512 \def\xintifFalseAelseB{\romannumeral0\xintiiifzero}%
```

5.39 `\xintIsTrue`, `\xintIsFalse`

1.09c. Suppressed at 1.2o. They seem not to have been documented, fortunately.

```
513 %\let\xintIsTrue \xintIsNotZero
514 %\let\xintIsFalse\xintIsZero
```

5.40 `\xintNOT`

1.09c. But it should have been called `\xintNOT`, not `\xintNot`. Former denomination deprecated at 1.2o. Besides, the macro is now defined as ii-type.

```
515 \def\xintNOT{\romannumeral0\xintiiszero}%
```

5.41 `\xintAND`, `\xintOR`, `\xintXOR`

Added with 1.09a. But they used `\xintSgn`, etc... rather than `\xintiiSgn`. This brings `\xintNum` overhead which is not really desired, and which is not needed for use by `xintexpr.sty`. At 1.2o I modify them to use only ii macros. This is enough for sign or zeroness even for `xintfrac` format, as manipulated inside the `\xintexpr`. Big hesitation whether there should be however `\xintiiAND` outputting 1 or 0 versus an `\xintAND` outputting 1[0] versus 0[0] for example.

```
516 \def\xintAND {\romannumeral0\xintand }%

5.45 `\xintiiMax`

At 1.2m, a long-standing bug was fixed: `\xintiiMax` had the overhead of applying `\xintNum` to its arguments due to use of a sub-macro of `\xintGeq` code to which this overhead was added at some point.

And on this occasion I reduced even more number of times input is grabbed.

```

5.51 `\xintiiSquareRoot`

First done with 1.08.

1.1 added `\xintiiSquareRoot`.

1.1a added `\xintiiSqrtR`.

1.2f (2016/03/01-02-03) has rewritten the implementation, the underlying mathematics remaining about the same. The routine is much faster for inputs having up to 16 digits (because it does it all with `\numexpr` directly now), and also much faster for very long inputs (because it now fetches only the needed new digits after the first 16 (or 17) ones, via the geometric sequence 16, then 32, then 64, etc...; earlier version did the computations with all remaining digits after a suitable starting point with correct 4 or 5 leading digits). Note however that the fetching of tokens is via intrinsically $O(N^2)$ macros, hence inevitably inputs with thousands of digits start being treated less well.

Actually there is some room for improvements, one could prepare better input X for the upcoming treatment of fetching its digits by 16, then 32, then 64, etc...

Incidentally, as `\xintiiSqrt` uses subtraction and subtraction was broken from 1.2 to 1.2c, then for another reason from 1.2c to 1.2f, it could get wrong in certain (relatively rare) cases. There was also a bug that made it unneedlessly slow for odd number of digits on input.

1.2f also modifies `\xintFloatSqrt` in `xintfrac.sty` which now has more code in common with here and benefits from the same speed improvements.

1.2k belatedly corrects the output to $\{1\}\{1\}$ and not 11 when input is zero. As braces are used in all other cases they should have been used here too.

Also, 1.2k adds an `\xintiSqrtR` macro, for coherence as `\xintiSqrt` is defined (and mentioned in user manual.)

5.53 \xintiibinomial

2015/11/28-29 for 1.2f.

2016/11/19 for 1.2h: I truly can't understand why I hard-coded last year an error-message for arguments outside of the range for binomial formula. Naturally there should be no error but a rather a 0 return value for binomial(x,y), if $y < 0$ or $x < y$!

I really lack some kind of infinity or NaN value.

1.2o deprecates \xintiibinomial. (which xintfrac.sty redefined to use \xintNum)

$y=x-k+1$. $j=1$. k . On va évaluer par $y/1*(y+1)/2*(y+2)/3$ etc... On essaie de regrouper de manière à utiliser au mieux `\numexpr`. On peut aller jusqu'à $x=10000$ car $9999*10000 < 10^8$. $463*464*465=99896880$, $98*99*100*101=97990200$. On va vérifier à chaque étape si on dépasse un seuil. Le style de l'implémentation diffère de celui que j'avais utilisé pour `\xintiiFac`. On pourrait tout-à-fait avoir une `verybigloop`, mais bon. Je rajoute aussi un `verysmall`. Le traitement est un peu différent pour elle afin d'aller jusqu'à $x=29$ (et pas seulement 26 si je suivais le modèle des autres, mais je veux pouvoir faire `binomial(29,1)`, `binomial(29,2)`, ... en `vsmall`).

y.j.k. La partie very small. y est au plus 26 (non 29 mais retesté dans \XINT_binom_vsmallloop_a), et tous les binomial(29,n) sont $<10^8$. On peut donc faire $y(y+1)(y+2)(y+3)$ et aussi il y a le fait que etex fait $a*b/c$ en double precision. Pour ne pas bifurquer à la fin sur smallloop, si $n=27, 27$, ou 29 on procède un peu différemment des autres boucles. Si je testais aussi #1 après #3-#2 pour les autres il faudrait des terminaisons différentes.

5.61 (WIP) \xintiiRandRangeAtoB

1.3b. Support for randrange() function.

We do it f-expandably for matters of `\xintNewExpr` etc... The `\xintexpr` will add `\xintNum` wrapper to possible fractional input. But `\xintiexpr` will call as is.

TODO: ? implement third argument (STEP) TODO: `\xintNum` wrapper (which truncates) not so good in `floatexpr`. Use `round`?

It is an error if $b \leq a$, as in Python.

```

This raises following annex question: immediately after setting the seed is it possible for `\xintUniformDeviate{N}` where $N > 0$ has exactly eight digits to return either 0 or $N-1$? It could be that this is never the case, then there is a bias in `randrange()`. Of course there are anyhow only 2^{28} seeds so `randrange(10^X)` is by necessity biased when executed immediately after setting the seed, if X is at least 9.

```

```

Here too, overhead is not such a problem. The idea is that we got by extraordinary same first 8 digits as upper range bound so we pick at random the remaining needed digits in one go and compare with the upper bound. If too big, we start again with another random 8 leading digits in given range. No need to aim at any kind of efficiency for the check and loop back.

---	--

The commenting is currently (2019/09/10) very sparse.

The macros from 1.08 (2013/06/07) remained unchanged until their complete rewrite at 1.2m (2019/07/31).

At 1.2n dependencies on *xintcore* were removed, so now the package loads only *xintkernel* (this could have been done earlier).

Also at 1.2n, macros evolved again, the main improvements being in the increased allowable sizes of the input for `\xintDecToHex`, `\xintDecToBin`, `\xintBinToHex`. Use of `\csname` governed expansion at some places rather than `\numexpr` with some clean-up after it.

6.1 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

136 }%

```

The 1.2n inserted exclamations marks, which when bumping back from `\XINT_dthb_again` gave rise to a `\numexpr`-loop which gathered the ! delimited arguments and inserted `\expandafter\XINT_dthb_update\the\numexpr` dynamically. The 1.2o trick is to insert it here immediately. Then at `\XINT_dthb_again` the `\numexpr` will trigger an already prepared chain.

The crux of the thing is handling of #3 at `\XINT_dthb_update_a`.

```

137 \def\XINT_dthb_exclam {!\XINT_dthb_exclam\relax

We only clean-up up to 3 zero hexadecimal digits, as output was produced in chunks of 4 hex digits. If input had no leading zero, output will have none either. If input had many leading zeroes, output will have some number (unspecified, but a recipe can be given...) of leading zeroes...

The coding is for varying a bit, I did not check if efficient, it does not matter.

6.7 \xintHexToDec

Completely (and belatedly) rewritten at 1.2m in the 1.2 style.

1.2m version robust against non terminated inputs, but there is no primitive from TeX which may generate hexadecimal digits and provoke expansion ahead, afaik, except of course if decimal digits are treated as hexadecimal. This robustness is not on purpose but from need to expand argument and then grab it again. So we do it safely.

Increased maximal size at 1.2n.

1.2m version robust against non terminated inputs.

An input without leading zeroes gives an output without leading zeroes.

```

It is a bit annoying to grab all to the end here. I have a version, modeled on the 1.2n variant of `\xintDecToHex` which solved that problem there, but it did not prove enough if at all faster in my brief testing and it had the defect of a reduced maximal allowed size of the input.

7 Package [xintgcd](#) implementation

.1	Catcodes, ε -TeX and reload detection . . .	166	.7	<code>\xintBezoutAlgorithm</code>	174
.2	Package identification	167	.8	<code>\xintGCDof</code>	176
.3	<code>\xintGCD</code> , <code>\xintiiGCD</code>	167	.9	<code>\xintLCMof</code>	176
.4	<code>\xintLCM</code> , <code>\xintiiLCM</code>	168	.10	<code>\xintTypesetEuclideanAlgorithm</code>	176
.5	<code>\xintBezout</code>	168	.11	<code>\xintTypesetBezoutAlgorithm</code>	177
.6	<code>\xintEuclideanAlgorithm</code>	172			

The commenting is currently (2019/09/10) very sparse. Release 1.09h has modified a bit the `\xintTypesetEuclideanAlgorithm` and `\xintTypesetBezoutAlgorithm` layout with respect to line indentation in particular. And they use the `xinttools` `\xintloop` rather than the Plain TeX or \mathbb{E} TeX's `\loop`.

Since 1.1 the package only loads `xintcore`, not `xint`. And for the `\xintTypesetEuclideanAlgorithm` and `\xintTypesetBezoutAlgorithm` macros to be functional the package `xinttools` needs to be loaded explicitly by the user.

Breaking change at 1.2p: `\xintBezout{A}{B}` formerly had output $\{A\}{B}\{U\}{V}\{D\}$ with $AU-BV=D$, now it is $\{U\}{V}\{D\}$ with $AU+BV=D$.

7.1 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

7.5 `\xintBezout`

`\xintBezout{#1}{#2}` produces $\{U\}\{V\}\{D\}$ with $UA+VB=D$, $D = \text{PGCD}(A,B)$ (non-positive), where #1 and #2 f-expand to big integers A and B.

I had not checked this macro for about three years when I realized in January 2017 that `\xintBezout{A}{B}` was buggy for the cases $A = 0$ or $B = 0$. I fixed that blemish in 1.2l but overlooked the other blemish that `\xintBezout{A}{B}` with A multiple of B produced a coefficient U as -0 in place of 0 .

Hence I rewrote again for 1.2p. On this occasion I modified the output of the macro to be `{U}{V}{D}` with $AU+BV=D$, formerly it was `{A}{B}{U}{V}{D}` with $AU - BV = D$. This is quite breaking change!

Note in particular change of sign of V .

I don't know why I had designed this macro to contain `{A}{B}` in its output. Perhaps I initially intended to output `{A//D}{B//D}` (but forgot), as this is actually possible from outcome of the last iteration, with no need of actually dividing. Current code however arranges to skip this last update, as U and V are already furnished by the iteration prior to realizing that the last non-zero remainder was found.

Also 1.2l raised `InvalidOperation` if both A and B vanished, but I removed this behaviour at 1.2p.

      q(n) quotient de r(n-1) par r(n)

```

```

si reste nul, exit et renvoie U = -e*uu, V = e*vv, A*U+B*V=D
sinon mise à jour
    vv, v = q * vv + v, vv
    uu, u = q * uu + u, uu
    e = -e

```

puis calcul quotient reste et itération

We arrange for `\xintiiMul` sub-routine to be called only with positive arguments, thus skipping some un-needed sign parsing there. For that though we have to screen out the special cases A divides B, or B divides A. And we first want to exchange A and B if $A < B$. These special cases are the only one possibly leading to U or V zero (for A and B positive which is the case here.) Thus the general case always leads to non-zero U and V's and assigning a final sign is done simply adding a - to one of them, with no fear of producing -0.

We use the fact that the `\romannumeral-`0` (or equivalent) done by `\xintiiadd` will absorb the initial space token left by `\XINT_mul_plusplus` in its output.

We arranged for operands here to be always positive which is needed for `\XINT_mul_plusplus` entry point (last time I checked...). Admittedly this kind of optimization is not good for maintenance of code, but I can't resist temptation of limiting the shuffling around of tokens...

7.11 \xintTypesetBezoutAlgorithm

Pour Bezout on a: $\{N\}\{A\}\{0\}\{1\}\{D=r(n)\}\{B\}\{1\}\{0\}\{q1\}\{r1\}\{\alpha1=q1\}\{\beta1=1\}$
 $\{q2\}\{r2\}\{\alpha2\}\{\beta2\}\dots\{qN\}\{rN=0\}\{\alphaN=A/D\}\{\betaN=B/D\}$

Donc $4N+8$ termes: $U1 = N$, $U2 = A$, $U5 = D$, $U6 = B$, $q1 = U9$, $qn = U\{4n+5\}$, n au moins 1
 $rn = U\{4n+6\}$, n au moins -1

$\alpha(n) = U\{4n+7\}$, n au moins -1

$\beta(n) = U\{4n+8\}$, n au moins -1

1.09h uses \xintloop, and \par rather than \endgraf; and no more \parindent0pt

```

8.1 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from ΗΕΙΚΟ ΟΒΕΡΔΙΕΚ's packages, then modified. The method for catcodes was also initially directly inspired by these packages.

```

8.5 \XINT_outfrac

Months later (2014/10/22): perhaps I should document what this macro does before I forget? from $\{e\}\{N\}\{D\}$ it outputs $N/D[e]$, checking in passing if $D=0$ or if $N=0$. It also makes sure D is not < 0 . I am not sure but I don't think there is any place in the code which could call `\XINT_outfrac` with a $D < 0$, but I should check.

```

8.6 \XINT_inFrac

Parses fraction, scientific notation, etc... and produces $\{n\}{A}{B}$ corresponding to A/B times 10^n . No reduction to smallest terms.

Extended in 1.07 to accept scientific notation on input. With lowercase e only. The `\xintexpr` parser does accept uppercase E also. Ah, by the way, perhaps I should at least say what this macro does? (belated addition 2014/10/22...), before I forget! It prepares the fraction in the internal format `{exponent}{Numerator}{Denominator}` where Denominator is at least 1.

2015/10/09: this venerable macro from the very early days (1.03, 2013/04/14) has gotten a lifting for release 1.2. There were two kinds of issues:

- 1) use of `\W`, `\Z`, `\T` delimiters was very poor choice as this could clash with user input,
- 2) the new `\XINT_frac_gen` handles macros (possibly empty) in the input as general as `\A.\Be\C\D.\Ee\F`. The earlier version would not have expanded the `\B` or `\E`: digits after decimal mark were constrained to arise from expansion of the first token. Thus the 1.03 original code would have expanded only `\A`, `\D`, `\C`, and `\F` for this input.

This reminded me think I should revisit the remaining earlier portions of code, as I was still learning TeX coding when I wrote them.

Also I thought about parsing even faster the $A/B[N]$ input, not expanding B, but this turned out to clash with some established uses in the documentation such as `1/\xintiiSqr{...}[0]`. For the implementation, careful here about potential brace removals with parameter patterns such as like `#1/#2#3[#4]` for example.

While I was at it 1.2 added `\numexpr` parsing of the N, which earlier was restricted to be only explicit digits. I allowed `[]` with empty N, but the way I did it in 1.2 with `\the\numexpr 0#1` was buggy, as it did not allow `#1` to be a `\count` for example or itself a `\numexpr` (although such inputs were not previously allowed, I later turned out to use them in the code itself, e.g. the float factorial of version 1.2f). The better way would be `\the\numexpr#1+\xint_c_` but 1.2f finally does only `\the\numexpr #1` and `#1` is not allowed to be empty.

The 1.2 `\XINT_frac_gen` had two locations with such a problematic `\numexpr 0#1` which I replaced for 1.2f with `\numexpr#1+\xint_c_`.

Regarding calling the macro with an argument $A[\langle\text{expression}\rangle]$, a / in the expression must be suitably hidden for example in `\firstofone` type constructs.

Note: when the numerator is found to be zero `\XINT_inFrac` *always* returns $\{0\}{0}\{1\}$. This behaviour must not change because 1.2g `\xintFloat` and `XINTinFloat` (for example) rely upon it: if the denominator on output is not 1, then `\xintFloat` assumes that the numerator is not zero.

As described in the manual, if the input contains a (final) $[N]$ part, it is assumed that it is in the shape $A[N]$ or $A/B[N]$ with A (and B) not containing neither decimal mark nor scientific part, moreover B must be positive and A have at most one minus sign (and no plus sign). Else there will be errors, for example $-0/2[0]$ would not be recognized as being zero at this stage and this could cause issues afterwards. When there is no ending $[N]$ part, both numerator and denominator will be parsed for the more general format allowing decimal digits and scientific part and possibly multiple leading signs.

1.2l fixes frailty of `\XINT_infrac` (hence basically of all `xintfrac` macros) respective to non terminated `\numexpr` input: `\xintRaw{\the\numexpr1}` for example. The issue was that `\numexpr` sees the / and expands what's next. But even `\numexpr 1//` for example creates an error, and to my mind this is a defect of `\numexpr`. It should be able to trace back and see that / was used as delimiter not as operator. Anyway, I thus fixed this problem belatedly here regarding `\XINT_infrac`.

8.7 \XINT_frac_gen

Extended in 1.07 to recognize and accept scientific notation both at the numerator and (possible) denominator. Only a lowercase e will do here, but uppercase E is possible within an `\xintexpr.. \relax`

Completely rewritten for 1.2 2015/10/10. The parsing handles inputs such as `\A.\Be\C\D.\Ee\F` where each of `\A`, `\B`, `\D`, and `\E` may need f-expansion and `\C` and `\F` will end up in `\numexpr`.

1.2f corrects an issue to allow `\C` and `\F` to be `\count` variable (or expressions with `\numexpr`):
 1.2 did a bad `\numexpr0#1` which allowed only explicit digits for expanded `#1`.

8.29 \xintTFrac

1.09i, for frac in \xintexpr. And \xintFrac is already assigned. T for truncation. However, potentially not very efficient with numbers in scientific notations, with big exponents. Will have to think it again some day. I hesitated how to call the macro. Same convention as in maple, but some people reserve fractional part to $x - \text{floor}(x)$. Also, not clear if I had to make it negative (or zero) if $x < 0$, or rather always positive. There should be in fact such a thing for each rounding function, trunc, round, floor, ceil.

```

8.30 \xintTrunc, \xintiTrunc

1.2i release notes: ever since its inception this macro was stupid for a decimal input: it did not handle it separately from the general fraction case $A/B[N]$ with $B > 1$, hence ended up doing divisions by powers of ten. But this meant that nesting \xintTrunc with itself was very inefficient.

1.2i version is better. However it still handles $B > 1$, $N < 0$ via adding zeros to B and dividing with this extended B. A possibly more efficient approach is implemented in \xintXTrunc, but its logic is more complicated, the code is quite longer and making it f-expandable would not shorten it... I decided for the time being to not complicate things here.

8.34 \xintXTrunc

1.09j [2014/01/06] This is completely expandable but not f-expandable. Rewritten for 1.2i (2016/12/04):

- no more use of \xintloop from xinttools.sty (replaced by \xintreplicate... from xintkernel.sty),
 - no more use in 0>N>-D case of a dummy control sequence name via \csname...\endcsname
 - handles better the case of an input already a decimal number
- Need to transfer code comments into public dtx.

8.63 Floating point macros

For a long time the float routines dating back to releases [1.07/1.08a](#) (May–June 2013) were not modified.

Since 1.2f (March 2016) the four operations first round their arguments to `\xinttheDigits`-floats (or P -floats), not `(\xinttheDigits+2)`-floats or $(P+2)$ -floats as was the case with earlier releases.

The four operations addition, subtraction, multiplication, division have always produced the correct rounding of the theoretical exact value to P or `\xinttheDigits` digits when the inputs are decimal numbers with at most P digits, and arbitrary decimal exponent part.

From 1.08a to 1.2j, `\xintFloat` (and `\XINTinFloat` which is used to parse inputs to other float macros) handled a fractional input A/B via an initial replacement to A'/B' where A' and B' were A and B truncated to $Q+2$ digits (where asked-for precision is Q), and then they correctly rounded A/B to Q digits. But this meant that this rounding of the input could differ (by up to one unit in the last place) from the correct rounding of the original A/B to the asked-for number of digits (which until 1.2f in uses as auxiliary to the macros for the basic operations was 2 more than the prevailing precision).

Since 1.2k all inputs are correctly rounded to the asked-for number of digits (this was, I think, the case in the 1.07 release -- there are no code comments -- but was, afaicr, not very efficiently done, and this is why the 1.08a release opted for truncation of the numerator and denominator.)

Notice that in float expressions, the `/` is treated as operator, hence the above discussion makes a difference only for the special input form `qfloat(A/B)` or for an `\xintexpr A/B\relax` embedded in the float expression, with A or B having more digits than the prevailing float precision.

Internally there is no inner representation of P -floats as such !!!!!

The input parser will again compute the length of the mantissa on each use !!! This is obviously something that must be improved upon before implementation of higher functions.

Currently, special tricks are used to quickly recognize inputs having no denominators, or fractions whose numerators and denominators are not too long compared to the target precision P , and in particular P -floats or quotients of two such.

Another long-standing issue is that float multiplication will first compute the $2P$ or $2P-2$ digits of the exact product, and then round it to P digits. This is sub-optimal for large P particularly as the multiplication algorithm is basically the schoolbook one, hence worse than quadratic in the \TeX implementation which has extra cost of fetching long sequences of tokens.

8.64 `\xintDigits`, `\xintSetDigits`

1.3f modifies the (strange) original signature `#1#2` for `\xintDigits` macro into `#1=`, allowing usage without colon. It also adds `\xintSetDigits`. Starred variants are added by `xintexpr.sty`.

```
1854 \mathchardef\XINTdigits 16
1855 \def\xintDigits #1=%
1856   {\afterassignment \xint_gobble_i \mathchardef\XINTdigits=%}
1857 \def\xinttheDigits {\number\XINTdigits }%
1858 \def\xintSetDigits #1{\mathchardef\XINTdigits=\numexpr#1\relax}%
```

8.65 `\xintFloat`

1.2f and 1.2g brought some refactoring which resulted in faster treatment of decimal inputs. 1.2i dropped use of some old routines dating back to pre 1.2 era in favor of more modern `\xintDSRr` for rounding. Then 1.2k improves again the handling of denominators B with few digits.

But the main change with 1.2k is a complete rewrite of the $B>1$ case in order to achieve again correct rounding in all cases.

The original version from 1.07 (May 2013) computed the exact rounding to P digits for all inputs. But from 1.08 on (June 2013), the macro handled A/B input by first truncating both A and B to at most

P+2 digits. This meant that decimal input (arbitrarily long, with scientific part) was correctly rounded, but in case of fractional input there could be up to 0.6 unit in the last place difference of the produced rounding to the input, hence the output could differ from the correct rounding.

Example with 16 digits (the default): `\xintFloat {1/17597472569900621233}`

with `xintfrac 1.07`: 5.682634230727187e-20

with `xintfrac 1.08b--1.2j`: 5.682634230727188e-20

with `xintfrac 1.2k`: 5.682634230727187e-20

The exact value is 5.682634230727187499924124...e-20, showing that 1.07 and 1.2k produce the correct rounding.

Currently the code ends in a more costly branch in about 1 case among 500, where it does some extra operations (a multiplication in particular). There is a free parameter delta (here set at 4), I have yet to make some numerical explorations, to see if it could be favorable to set it to a higher value (with delta=5, there is only 1 exceptional case in 5000, etc...).

I have always hesitated about the policy of printing 10.00...0 in case of rounding upwards to the next power of ten. Already since 1.2f `\XINTinFloat` always produced a mantissa with exactly P digits (except for the zero value). Starting with 1.2k, `\xintFloat` drops this habit of printing 10.00...0 in such cases. Side note: the rounding-up detection worked when the input A/B was with numerator A and denominator B having each less than P+2 digits, or with B=1, else, it could happen that the output was a power of ten but not detected to be a rounding up of the original fraction. The value was ok, but printed 1.0...0eN with P-1 zeroes, not 10.0...0e(N-1).

I decided it was not worth the effort to enhance the algorithm to detect with 100% fiability all cases of rounding up to next power of ten, hence 1.2k dropped this.

To avoid duplication of code, and any extra burden on `\XINTinFloat`, which is the macro used internally by the float macros for parsing their inputs, we simply make now `\xintFloat` a wrapper of `\XINTinFloat`.

8.66 \XINTinFloat, \XINTinFloatS, \XINTiLogTen

This routine is like `\xintFloat` but produces an output of the shape $A[N]$ which is then parsed faster as input to other float macros. Float operations in `\xintfloatexpr...` relax use internally this format.

It must be used in form `\XINTinFloat[P]{f}`: the optional $[P]$ is mandatory.

Since 1.2f, the mantissa always has exactly P digits even in case of rounding up to next power of ten. This simplifies other routines.

1.2g added a variant `\XINTinFloatS` which, in case of decimal input with less than the asked for precision P will not add extra zeros to the mantissa. For example it may output $2[0]$ even if $P=500$, rather than the canonical representation $200...000[-499]$. This is how `\xintFloatMul` and `\xintFloatDiv` parse their inputs, which speeds-up follow-up processing. But `\xintFloatAdd` and `\xintFloatSub` still use `\XINTinFloat` for parsing their inputs; anyway this will have to be changed again when inner structure will carry upfront at least the length of mantissa as data.

Each time `\XINTinFloat` is called it at least computes a length. Naturally if we had some format for floats that would be dispensed of...

something like `<letterP><length of mantissa>.mantissa.exponent`, etc... not yet.

Since 1.2k, `\XINTinFloat` always correctly rounds its argument, even if it is a fraction with very big numerator and denominator. See the discussion of `\xintFloat`.

1.3e adds `\XINTiLogTen`.

Ici #1=P-L est >0. L'exposant sera N-(P-L). #2=A. #3=P. #4=N.
18 mars 2016. En fait dans certains contextes il est sous-optimal d'ajouter les zéros. Par exemple quand c'est appelé par la multiplication ou la division, c'est idiot de convertir 2 en 200000...00000[-499]. Donc je redéfinis addzeros en needzeroes. Si on appelle sous la forme \XINTinFloatS, on ne fait pas l'addition de zeros.

```
1964 \def\XINT_infloat_sp_needzeros #1.#2.#3.#4.{!#1.#2[#4]}%

$\epsilon Q.P. |B|. |A|. n. \{A\}\{B\}$

`\xintDSH{-x}{U}` multiplies U by 10^x . When x is negative, this means it truncates (i.e. it drops the last -x digits).

We don't try to optimize too much macro calls here, the odds are 2 per 1000 for this branch to be taken. Perhaps in future I will use higher free parameter d, which currently is set at 4.

8.67 `\xintPFloat`

1.1. This is a prettifying printing macro for floats.

The macro applies one simple rule: `x.yz...eN` will drop scientific notation in favor of pure decimal notation if $-5 < N \leq 5$. This is the default behaviour of Maple. The N here is as produced on output by `\xintFloat`.

Special case: the zero value is printed 0. (with a dot)

The coding got simpler with 1.2k as its `\xintFloat` always produces a mantissa with exactly P digits (no more `10.0...0eN` annoying exception).

```

8.68 \XINTinFloatFracdigits

1.09i, for `frac` function in `\xintfloatexpr`. This version computes exactly from the input the fractional part and then only converts it into a float with the asked-for number of digits. I will have to think it again some day, certainly.

1.1 removes optional argument for which there was anyhow no interface, for technical reasons having to do with `\xintNewExpr`.

1.1a renames the macro as `\XINTinFloatFracdigits` (from `\XINTinFloatFrac`) to be synchronous with the `\XINTinFloatSqrt` and `\XINTinFloat` habits related to `\xintNewExpr` problems.

Note to myself: I still have to rethink the whole thing about what is the best to do, the initial way of going through `\xintfrac` was just a first implementation.

```

```

8.69 \xintFloatAdd, \XINTinFloatAdd

First included in release 1.07.

1.09ka improved a bit the efficiency. However the `add`, `sub`, `mul`, `div` routines were provisory and supposed to be revised soon.

Which didn't happen until 1.2f. Now, the inputs are first rounded to `P` digits, not `P+2` as earlier.

8.71 \xintFloatMul, \XINTinFloatMul

1.07.

Starting with 1.2f the arguments are rounded to the target precision P not P+2.

1.2g handles the inputs via \XINTinFloatS which will be more efficient when the precision is large and the input is for example a small constant like 2.

1.2k does a micro improvement to the way the macro passes over control to its output routine (former version used a higher level \xintE causing some extra un-needed processing with two calls to \XINT_infrac where one was amply enough).

```

8.74 \xintFloatPow, \XINTinFloatPow

1.07: initial version. 1.09j has re-organized the core loop.

2015/12/07. I have hesitated to map $^$ in expressions to \xintFloatPow rather than \xintFloatPower. But for 1.234567890123456 to the power 2145678912 with P=16, using Pow rather than Power seems to bring only about 5% gain.

This routine requires the exponent x to be compatible with \numexpr parsing.

1.2f has rewritten the code for better efficiency. Also, now the argument A for A^x is first rounded to P digits before switching to the increased working precision (which depends upon x).

```

This ending is common with `\xintFloatPower`.

In the case of negative exponent we need to inverse the Q-digits mantissa. This requires no special attention now as 1.2k's `\xintFloat` does correct rounding of fractions hence it is easy to bound the total error. It can be checked that the algorithm after final rounding to the target precision computes a value Z whose distance to the exact theoretical will be less than 0.52 ulp(Z) (and worst cases can only be slightly worse than 0.51 ulp(Z)).

In the case of the half-integer exponent (only via the expression interface,) the computation (which proceeds via `\XINTinFloatPowerH`) ends with a square root. This square root extraction is done with 3 guard digits (the power operations were done with more.) Then the value is rounded to the target precision. There is thus this rounding to 3 guard digits (in the case of negative exponent the reciprocal is computed before the square-root), then the square root is (computed with exact rounding for these 3 guard digits), and then there is the final rounding of this to the target precision. The total error (for positive as well as negative exponent) has been estimated to at worst possibly exceed slightly 0.5125 ulp(Z), and at any rate it is less than 0.52 ulp(Z).

8.75 `\xintFloatPower`, `\XINTinFloatPower`

1.07. The core loop has been re-organized in 1.09j for some slight efficiency gain. The exponent B is given to `\xintNum`. The `^` in expressions is mapped to this routine.

Same modifications as in `\xintFloatPow` for 1.2f.

1.2f adds a special private macro for allowing half-integral exponents for use with \wedge within `\xintfloatexpr`. The exponent will be first truncated to either an integer or an half-integer. The macro is not for general use.

1.2k does anew this 1.2f handling of half-integer exponents for the `\xintfloatexpr` parser: with 1.2f's code the final square-root extraction was applied to a value already rounded to the target precision, unneedlessly losing precision.

```
2463 \def\xintFloatPower    {\romannumeral0\xintfloatpower}%
2464 \def\xintfloatpower #1{\XINT_flpower_chkopt \xintfloat #1\xint:}%

2466 \def\XINTinfloatpower #1{\XINT_flpower_chkopt \XINTinfloatS #1\xint:}%
```

First the special macro for use by the expression parser which checks if one raises to an half-integer exponent. This is always with `\XINTdigits` precision. Rewritten for 1.2k in order for the final square root to keep three guard digits.

We have to be careful that exponent #2 is not constrained by TeX bound. And we must allow fractions. The 1.2k variant does a rounding to nearest integer of half-integer, 1.2f did a truncation rather (this is done after truncation of #2 to fixed point with one digit after mark.) We try to recognize quickly the case of integer exponent, for speed, but there is overhead of going through `\xintiTrunc1`.

```

Computations are done with Q blocks of eight digits. When a multiplication has a carry, hence creates Q+1 blocks, the least significant one is dropped. The goal is to compute an approximate value X' to the exact value X, such that the final relative error (X-X')/X will be at most 10^{-P} with P the desired precision. Then, when we round X' to X'' with P significant digits, we can prove that the absolute error |X-X''| is bounded (strictly) by 0.6 ulp(X''). (ulp= unit in the last (significant) place). Let N be the number of such operations, the formula for Q deduces from the previous explanations is that 8Q should be at least P+9+k, with k the number of digits of N (in base 10). Note that 1.2 version used P+10+k, for 1.2f I reduced to P+9+k. Also, k should be the

number of digits of the number N of multiplications done, hence for $n \leq 10000$ we can take $N = n/2$, or $N/3$, or $N/4$. This is rounded above by `numexpr` and always an overestimate of the actual number of approximate multiplications done (the first ones are exact). (vérifier ce que je raconte, j'ai la flemme là).

We then want $\text{ceil}((P+k+n)/8)$. Using `\numexpr` rounding division (ARRRRRGGGHHHH), if m is a positive integer, $\text{ceil}(m/8)$ can be computed as $(m+3)/8$. Thus with $m = P+10+k$, this gives $Q < -(P+13+k)/8$. The routine actually computes $8(Q-1)$ for use in `\XINT_FL_fac_addzeros`.

With 1.2f the formula is $m = P+9+k$, $Q < -(P+12+k)/8$, and we use now $4 = 12-8$ rather than the earlier $5 = 13-8$. Whatever happens, the value computed in `\XINT_FL_fac_increaseP` is at least 8. There will always be an extra block.

Note: with `Digits:=32`; Maple gives for $200!$:

```
> factorial(200.);
375
```

```
0.78865786736479050355236321393218 10
```

My 1.2f routine (and also 1.2) outputs:

```
7.8865786736479050355236321393219e374
```

and this is the correct rounding because for 40 digits it computes

```
7.886578673647905035523632139321850622951e374
```

Maple's result (contrarily to `xint`) is thus not the correct rounding but still it is less than 0.6 ulp wrong.

This is the crucial ending. I note that I used here an `\ifnum` test rather than the `gob_til_eightzeroes` thing. Actually for eight digits there is much less difference than for only four.

The "carry" situation is marked by a final `!-1` rather than `!-2` for no-carry. (a `\numexpr` must be stopped, and leaving a `-` as delimiter is good as it will not arise earlier.)

8.77 `\xintFloatPFactorial`, `\XINTinFloatPFactorial`

2015/11/29 for 1.2f. Partial factorial `pfactorial(a,b)=(a+1)...`, only for non-negative integers with `a<=b<10^8`.

1.2h (2016/11/20) now avoids raising `\xintError:OutOfRangePFac` if the condition `0<=a<=b<10^8` is violated. Same as for `\xintiPFactorial`.

```

```

See the comments for `\XINT_FL_pfac_increaseP`. Case of $b=a+1$ should be filtered out perhaps. We only needed here to copy the `\xintPFfactorial` macros and re-use `\XINT_FL_fac_mul/\XINT_FL_fac_out`.

Had to modify a bit `\XINT_FL_pfac_addzeroes`. We can enter here directly with #3 equal to specify the precision (the calculated value before final rounding has a relative error less than $\#3 \cdot 10^{\{-\#4-1\}}$), and #5 would hold the macro doing the final rounding (or truncating, if I make a `FloatTrunc` available) to a given number of digits, possibly not #4. By default the #3 is 1, but `FloatBinomial` calls it with #3=4.

8.78 \xintFloatBinomial, \XINTinFloatBinomial

1.2f. We compute $\text{binomial}(x,y)$ as $\text{pfac}(x-y,x)/y!$, where the numerator and denominator are computed with a relative error at most $4 \cdot 10^{-2}$, then rounded (once I have a float truncation, I will use truncation rather) to $P+3$ digits, and finally the quotient is correctly rounded to P digits. This will guarantee that the exact value X differs from the computed one Y by at most $0.6 \text{ ulp}(Y)$. (2015/12/01).

2016/11/19 for 1.2h. As for `\xintiiBinomial`, hard to understand why last year I coded this to raise an error if $y < 0$ or $y > x$! The question of the Gamma function is for another occasion, here x and y must be (small) integers.

8.79 \xintFloatSqrt, \XINTinFloatSqrt

First done for 1.08.

The float version was developed at the same time as the integer one and even a bit earlier. As a result the integer variant had some sub-optimal parts. Anyway, for 1.2f I have rewritten the integer variant, and the float variant delegates all preparatory work for it until the last step. In particular the very low precisions are not penalized anymore from doing computations for at least 17 or 18 digits. Both the large and small precisions give quite shorter computation times.

Also, after examining more closely the achieved precision I decided to extend the float version in order for it to obtain the correct rounding (for inputs already of at most P digits with P the precision) of the theoretical exact value.

Beyond about 500 digits of precision the efficiency decreases swiftly, as is the case generally speaking with xintcore/xint/xintfrac arithmetic macros.

Final note: with 1.2f the input is always first rounded to P significant places.

```

8.86 (WIP) \XINTinRandomFloatS, \XINTinRandomFloatSdigits

1.3b. Support for random() function.

Thus as it is a priori only for xintexpr usage, it expands inside \csname context, but as we need to get rid of initial zeros we use \xintRandomDigits not \xintXRandomDigits (\expanded would have a use case here).

And anyway as we want to be able to use random() in \xintdeffunc/\xintNewExpr, it is good to have f-expandable macros, so we add the small overhead to make it f-expandable.

We don't have to be very efficient in removing leading zeroes, as there is only 10% chance for each successive one. Besides we use (current) internal storage format of the type A[N], where A is not required to be with \xintDigits digits, so N will simply be -\xintDigits and needs no adjustment.

In case we use in future with #1 something else than \xintDigits we do the 0-(#1) construct.

I had some qualms about doing a random float like this which means that when there are leading zeros in the random digits the (virtual) mantissa ends up with trailing zeros. That did not feel right but I checked random() in Python (which of course uses radix 2), and indeed this is what happens there.

```

9.5 \xintPowerSeries

The 1.03 version was very lame and created a build-up of denominators. (this was at a time `\xintAdd` always multiplied denominators, by the way) The Horner scheme for polynomial evaluation is used in 1.04, this cures the denominator problem and drastically improves the efficiency of the macro. Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

9.7 \xintRationalSeries

This computes $F(a)+\dots+F(b)$ on the basis of the value of $F(a)$ and the ratios $F(n)/F(n-1)$. As in `\xintPowerSeries` we use an iterative scheme which has the great advantage to avoid denominator build-up. This makes exact computations possible with exponential type series, which would be completely inaccessible to `\xintSeries`. #1= a , #2= b , #3= $F(a)$, #4=ratio function Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

9.8 \xintRationalSeriesX

a,b,initial,ratiofunction,x

This computes $F(a,x)+\dots+F(b,x)$ on the basis of the value of $F(a,x)$ and the ratios $F(n,x)/F(n-1,x)$. The argument x is first expanded and it is the value resulting from this which is used then throughout. The initial term $F(a,x)$ must be defined as one-parameter macro which will be given x . Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

--	---

The commenting is currently (2019/09/10) very sparse. Release 1.09m (2014/02/26) has modified a few things: `\xintFtoCs` and `\xintCntoCs` insert spaces after the commas, `\xintCstoF` and `\xintCstoCv` authorize spaces in the input also before the commas, `\xintCntoCs` does not brace the produced coefficients, new macros `\xintFtoC`, `\xintCtoF`, `\xintCtoCv`, `\xintFGtoC`, and `\xintGGCFrac`.

There is partial dependency on *xinttools* due to `\xintCstoF` and `\xintCsToCv`.

10.1 Catcodes, ε -T_EX and reload detection

The code for reload detection was initially copied from HEIKO OBERDIEK's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

10.9 \xintFtoC

New in 1.09m: this is the same as `\xintFtoCx` with empty separator. I had temporarily during preparation of 1.09m removed braces from `\xintFtoCx`, but I recalled later why that was useful (see doc), thus let's just here do `\xintFtoCx {}`

```

10.25 \xintCntoCs

Modified in 1.09m: added spaces after the commas in the produced list. Moreover the coefficients are not braced anymore. A slight induced limitation is that the macro argument should not contain some explicit comma (cf. `\XINT_cntcs_exit_b`), hence `\xintCntoCs {\macro,}` with `\def\macro,#1{<stuff>}` would crash. Not a very serious limitation, I believe.

```

```

10.26 \xintCntoGC

Modified in 1.06 to give the N first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that.

1.09m maintains the braces, as the coeff are allowed to be fraction and the slash can not be naked in the GC format, contrarily to what happens in `\xintCntoCs`. Also the separators given to `\xintGCtoGCx` may then fetch the coefficients as argument, as they are braced.

This is release 1.3f of [2019/09/10].

11.1 Old comments

These general comments were last updated at the end of the 1.09x series in 2014. The principles remain in place to this day but refer to [CHANGES.html](#) for some significant evolutions since.

The first version was released in June 2013. I was greatly helped in this task of writing an expandable parser of infix operations by the comments provided in [13fp-parse.dtx](#) (in its version as available in April-May 2013). One will recognize in particular the idea of the ``until`` macros; I have not looked into the actual [13fp](#) code beyond the very useful comments provided in its documentation.

A main worry was that my data has no a priori bound on its size; to keep the code reasonably efficient, I experimented with a technique of storing and retrieving data expandably as *names* of control sequences. Intermediate computation results are stored as control sequences `\.=a/b[n]`.

Roughly speaking, the parser mechanism is as follows: at any given time the last found ``operator`` has its associated `until` macro awaiting some news from the token flow; first `getnext` expands forward in the hope to construct some number, which may come from a parenthesized sub-expression, from some braced material, or from a digit by digit scan. After this number has been formed the next operator is looked for by the `getop` macro. Once `getop` has finished its job, `until` is presented with three tokens: the first one is the precedence level of the new found operator (which may be an end of expression marker), the second is the operator character token (earlier versions had here already some macro name, but in order to keep as much common code to `expr` and `floatexpr` common as possible, this was modified) of the new found operator, and the third one is the newly found number (which was encountered just before the new operator).

The `until` macro of the earlier operator examines the precedence level of the new found one, and either executes the earlier operator (in the case of a binary operation, with the found number and a previously stored one) or it delays execution, giving the hand to the `until` macro of the operator having been found of higher precedence.

A minus sign acting as prefix gets converted into a (unary) operator inheriting the precedence level of the previous operator.

Once the end of the expression is found (it has to be marked by a `\relax`) the final result is output as four tokens (five tokens since 1.09j) the first one a catcode 11 exclamation mark, the second one an error generating macro, the third one is a protection mechanism, the fourth one

a printing macro and the fifth is `\.=a/b[n]`. The prefix `\xintthe` makes the output printable by killing the first three tokens.

11.2 Catcodes, ε -TeX and reload detection

The code for reload detection was initially copied from ΗΕΙΚΟ ΟΒΕΡΔΙΕΚ's packages, then modified.

The method for catcodes was also initially directly inspired by these packages.

11.12 \thexintexpr, \thexintiexpr, \thexintfloatexpr, \thexintiexpr

New with 1.2h. I have been for the last three years very strict regarding macros with `\xint` or `\XINT`, but well.

```
149 \let\thexintexpr      \xinttheexpr
150 \let\thexintiexpr    \xinttheiexpr
151 \let\thexintfloatexpr\xintthefloatexpr
152 \let\thexintiexpr    \xinttheiexpr
```

11.13 `\xinteval`, `\xintieval`, `\xintfloateval`, `\xintiieval`

```

153 \def\xinteval #1%
154   {\romannumeral`&&\expandafter\XINT_expr_print\romannumeral0\xintbareeval#1\relax}%
155 \def\xintieval #1%
156   {\romannumeral`&&\expandafter\xint_gobble_iii\romannumeral`&&\xintiexpr#1\relax}%
157 \def\xintfloateval #1%
158   {\romannumeral`&&\expandafter\xint_gobble_iii\romannumeral`&&\xintfloatexpr#1\relax}%
159 \def\xintiieval #1%
160   {\romannumeral`&&\expandafter\XINT_iiexpr_print\romannumeral0\xintbareiieval#1\relax}%

```

The «print» macros are made into inert entities when an expression is parsed by `\xintNewExpr` or `\xintdeffunc`. In order to allow usage of `\xinteval` et al., we need to replace them by the corresponding `\xintexpr` et al and drop the macro wrappers (because they do not expand and will trap the expression parser). The behaviour of `\xinteval{3}7` will not be as in a normal expression but such syntax is anyhow obscure.

```

```

11.20 `\xintthecoords`

1.1 Wraps up an even number of comma separated items into pairs of TikZ coordinates; for use in the following way:

```
coordinates {\xintthecoords\xintfloatexpr ... \relax}
```

The crazyness with the `\csname` and `unlock` is due to TikZ somewhat STRANGE control of the TOTAL number of expansions which should not exceed the very low value of 100 !! As we implemented `\XINT_thecoords_b` in an "inline" style for efficiency, we need to hide its expansions.

Not to be used as `\xintthecoords\xintthefloatexpr`, only as `\xintthecoords\xintfloatexpr` (or `\xintiexpr` etc...). Perhaps `\xintthecoords` could make an extra check, but one should not accustom users to too loose requirements!

```

```

11.21 Locking and unlocking

Some renaming and modifications here with release 1.2 to switch from using chains of `\romannumeral-0` in order to gather numbers, possibly hexadecimals, to using a `\csname` governed expansion. In this way no more limit at 5000 digits, and besides this is a logical move because the `\xintexpr` parser is already based on `\csname...\endcsname` storage of numbers as one token.

The limitation at 5000 digits didn't worry me too much because it was not very realistic to launch computations with thousands of digits... such computations are still slow with 1.2 but less so now.

Chains or `\romannumeral` are still used for the gathering of function names and other stuff which I have half-forgotten because the parser does many things.

In the earlier versions we used the `lockscan` macro after a chain of `\romannumeral-`0` had ended gathering digits; this uses has been replaced by direct processing inside a `\csname...\endcsname` and the macro is kept only for matters of dummy variables.

Currently, the parsing of hexadecimal numbers needs two nested `\csname...\endcsname`, first to gather the letters (possibly with a hexadecimal fractional part), and in a second stage to apply `\xintHexToDec` to do the actual conversion. This should be faster than updating on the fly the number (which would be hard for the fraction part...).

```

11.25 \XINT_expr_scan_nbr_or_func: the integer or decimal number or hexa-decimal number or function name or variable name or special hacky things big parser

11.25.1	Integral part (skipping zeroes)	307
11.25.2	Fractional part	309
11.25.3	Scientific notation	310
11.25.4	Hexadecimal numbers	311
11.25.5	\XINT_expr_scanfunc: parsing names of functions and variables	312

1.2 release has replaced chains of \romannumeral-`0 by \csname governed expansion. Thus there is no more the limit at about 5000 digits for parsed numbers.

In order to avoid having to lock and unlock in succession to handle the scientific part and adjust the exponent according to the number of digits of the decimal part, the parsing of this decimal part counts on the fly the number of digits it encounters.

There is some slight annoyance with `\xintiexpr` which should never be given a `[n]` inside its `\csname.=<digits>\endcsname` storage of numbers (because its arithmetic uses the `ii` macros which know nothing about the `[N]` notation). Hence if the parser has only seen digits when hitting something else than the dot or `e` (or `E`), it will not insert a `[0]`. Thus we very slightly compromise the efficiency of `\xintexpr` and `\xintfloatexpr` in order to be able to share the same code with `\xintiexpr`.

Indeed, the parser at this location is completely common to all, it does not know if it is working inside `\xintexpr` or `\xintiexpr`. On the other hand if a dot or a `e` (or `E`) is met, then the (common) parser has no scruples ending this number with a `[n]`, this will provoke an error later if that was within an `\xintiexpr`, as soon as an arithmetic macro is used.

As the gathered numbers have no spaces, no pluses, no minuses, the only remaining issue is with leading zeroes, which are discarded on the fly. The hexadecimal numbers leading zeroes are stripped in a second stage by the `\xintHexToDec` macro.

With 1.2, `\xinttheexpr . \relax` does not work anymore (it did in earlier releases). There must be digits either before or after the decimal mark. Thus both `\xinttheexpr 1.\relax` and `\xinttheexpr .1\relax` are legal.

The ``` syntax is here used for special constructs like ``+`(..)`, ``*`(..)` where `+` or `*` will be treated as functions. Current implementation picks only one token (could have been braced stuff), here it will be `+` or `*`, and via `\XINT_expr_op_`` this then becomes a suitable `\XINT_{expr|iiexpr|fexpr}_func_+` (or `*`). Documentation says to use ``+`(...)`, but ``+(...)` is also valid. The opening parenthesis must be there, it is not allowed to come from expansion.

```

```

With 1.2d the tacit multiplication in front of a variable name or function name is now done with a higher precedence, intermediate between the common one of $*$ and $/$ and the one of $^$. Thus $x/2y$ is like $x/(2y)$, but x^2y is like x^2*y and $2y!$ is not $(2y)!$ but $2*y!$.

Finally, 1.2d has moved away from the `_scan` macros all the business of the tacit multiplication in one unique place via `\XINT_expr_getop`. For this, the ending token is not first given to `\string` as was done earlier before handing over back control to `\XINT_expr_getop`. Earlier we had to identify the catcode `11 !` signaling a sub-expression here. With no `\string` applied we can do it in `\XINT_expr_getop`. As a corollary of this displacement, parsing of big numbers should be a tiny bit faster now.

Extended for 1.2l to ignore underscore character `_` if encountered within digits; so it can serve as separator for better readability.

11.25.4 Hexadecimal numbers

1.2d has moved most of the handling of tacit multiplication to `\XINT_expr_getop`, but we have to do some of it here, because we apply `\string` before calling `\XINT_expr_scanhexI_aa`. I do not insert the `*` in `\XINT_expr_scanhexI_a`, because it is its higher precedence variant which will be expected, to do the same as when a non-hexadecimal number prefixes a sub-expression. Tacit multiplication in front of variable or function names will not work (because of this `\string`).

Extended for 1.2l to ignore underscore character `_` if encountered within digits.

```

This handles: 1) (indirectly) tacit multiplication by a variable in front a of sub-expression, 2) (indirectly) tacit multiplication in front of a \count etc..., 3) functions which are recognized via an encountered opening parenthesis (but later this must be disambiguated from variables with tacit multiplication) 4) 5) 6) 7) acceptable components of a variable or function names: @, underscore, digits, letters (or chars of category code letter.)

The short lived 1.2d which followed the even shorter lived 1.2c managed to introduce a bug here as it removed the check for catcode 11 !, which must be recognized if ! is not to be taken as part of a variable name. Don't know what I was thinking, it was the time when I was moving the handling of tacit multiplication entirely to the \XINT_expr_getop side. Fixed in 1.2e.

I almost decided to remove the \ifcat\relax test whose rôle is to avoid the \string#1 to do something bad is the escape char is a digit! Perhaps I will remove it at some point ! I truly almost did it, but also the case of no escape char is a problem (\string\0, if \0 is a count ...)

The (indirectly) above means that via \XINT_expr_func then \XINT_expr_op__ one goes back to \XINT_expr_getop then \XINT_expr_getop_b which is the location where tacit multiplication is now centralized. This makes the treatment of tacit multiplication for situations such as

<variable>\count or <variable>\xintexpr..
relax, perhaps a bit sub-optimal, but first the variable name must be gathered, second the variable must expand to its value.

Comments written 2015/11/12: earlier there was an `\ifcsname` test for checking if we had a variable in front of a `(`, for tacit multiplication for example in `x(y+z(x+w))` to work. But after I had implemented functions (that was yesterday...), I had the problem if was impossible to re-declare a variable name such as "f" as a function name. The problem is that here we can not test if the function is available because we don't know if we are in `expr`, `iiexpr` or `floatexpr`. The `\xint_c_xviii` causes all fetching operations to stop and control is handed over to the routines which will be `expr`, `iiexpr` ou `floatexpr` specific, i.e. the `\XINT_{expr|iiexpr|floatexpr}_op_{`|_}` which are invoked by the `until_<op>_b` macros earlier in the stream. Functions may exist for one but not the two other parsers. Variables are declared via one parser and usable in the others, but naturally `\xintiexpr` has its restrictions.

Thinking about this again I decided to treat a priori cases such as `x(...)` as functions, after having assigned to each variable a low-weight macro which will convert this into `_getop\.=<value of x>*(...)`. To activate that macro at the right time I could for this exploit the "onliteral" intercept, which is parser independent (1.2c).

This led to me necessarily to rewrite partially the `seq`, `add`, `mul`, `subs`, `iter` ... routines as now the variables fetch only one token. I think the thing is more efficient.

1.2c had `\def\XINT_expr_func #1(#2{\xint_c_xviii #2{#1}}`

In `\XINT_expr_func` the `#2` is `_` if `#1` must be a variable name, or `#2=` if `#1` must be either a function name or possibly a variable name which will then have to be followed by tacit multiplication before the opening parenthesis.

The `\xint_c_xviii` is there because `_op_` must know in which parser it works. Dispendious for `_`. Hence I modify for 1.2d.

```
578 \def\XINT_expr_func #1(#2{\if _#2\xint_dothis\XINT_expr_op__\fi
579   \xint_orthat{\xint_c_xviii #2}{#1}}%
```

11.26 `\XINT_expr_getop`: finding the next operator or closing parenthesis or end of expression

Release 1.1 implements multi-character operators.

1.2d adds tacit multiplication also in front of variable or functions names starting with a letter, not only a `@` or a `_` as was already the case. This is for `(x+y)z` situations. It also applies higher precedence in cases like `x/2y` or `x/2@`, or `x/2max(3,5)`, or `x/2\xintexpr 3\relax`.

In fact, finally I decide that all sorts of tacit multiplication will always use the higher precedence.

Indeed I hesitated somewhat: with the current code one does not know if `\XINT_expr_getop` as invoked after a closing parenthesis or because a number parsing ended, and I felt distinguishing the two was unneeded extra stuff. This means cases like `(a+b)/(c+d)(e+f)` will first multiply the last two parenthesized terms.

The ! starting a sub-expression must be distinguished from the post-fix ! for factorial, thus we must not do a too early \string. In versions < 1.2c, the catcode 11 ! had to be identified in all branches of the number or function scans. Here it is simply treated as a special case of a letter.

1.2q adds tacit multiplication in cases such as (1+1)3 or 5!7!

```

11.28 |, ||, &, &&, <, >, =, ==, <=, >=, !=, +, -, *, /, ^, **, //, /:, .., ..[,]..,][,][: ,:], and ++ operators

11.28.1	Square brackets for lists, the !? for omit and abort, and the ++ postfix construct	316
11.28.2	The , &, xor, <, >, =, <=, >=, !=, //, /:, .., +, -, *, /, ^, ..[, and].. operators for expr, floatexpr and iiexpr operators	318
11.28.3	The]+,]-,]*,]/,]^, +[, -[, *[, /[, and ^[list operators	320
11.28.4	The 'and', 'or', 'xor', and 'mod' as infix operator words	322
11.28.5	The , &&, **, **[,]** operators as synonyms	322

11.28.1 Square brackets for lists, the !? for omit and abort, and the ++ postfix construct

This is all very clever and only need setting some suitable precedence levels, if only I could understand what I did in 2014... just joking. Notice that `op_)` macros are defined here in the `\xintFor` loop.

There is some clever business going on here with the letter a for handling constructs such as `[3..5]*2` (I think...).

1.2c has replaced 1.1's private dealings with "`^C`" (which was done before dummy variables got implemented) by use of "`!?`". See discussion of omit and abort.

11.28.2 The |, &, xor, <, >, =, <=, >=, !=, //, /:, .., +, -, *, /, ^, ..[, and].. operators for expr, floatexpr and iexpr operators

1.2d needed some room between /, * and ^. Hence precedence for ^ is now at 9

11.29 Macros for list selectors: [list][N], [list][:b], [list][a:], [list][a:b]

11.29.1	\xintListSel:x:csv	325
11.29.2	\xintListSel:f:csv	326
11.29.3	\xintKeep:x:csv	327
11.29.4	\xintKeep:f:csv	328
11.29.5	\xintTrim:f:csv	328
11.29.6	\xintNthEltPy:f:csv	328
11.29.7	\xintLength:f:csv	328
11.29.8	\xintReverse:f:csv	328

Python slicing was first implemented for 1.1 (27 octobre 2014). But it used \xintCSVtoList and \xintListWithSep{,} to convert back and forth to token lists for use of \xintKeep, \xintTrim, \xintNthElt. Not very efficient! Also [list][a:b] was Python like but not [list][N] which counted items starting at one, and returned the length for N=0.

Release 1.2g changed this so [list][N] now counts starting at zero and len(list) computes the number of items. Also 1.2g had its own f-expandable macros handling directly the comma separated lists. They are located into [xinttools.sty](#).

1.2j improved the [xinttools.sty](#) macros and furthermore it made the Python slicing in expressions a bit more efficient still by exploiting in some cases that expansion happens in \csname...\endcsname and does not have to be f-expandable. But the f-expandable variants must be kept for use by \xintNewExpr and \xintdeffunc.

```

11.30 Macros for a..b list generation

11.30.1	<code>\xintSeq::csv</code>	328
11.30.2	<code>\xintiSeq::csv</code>	329

Ne produit que des listes d'entiers inférieurs à la borne de TeX ! mais sous la forme N/1[0] en ce qui concerne `\xintSeq::csv`.

11.30.1 \xintSeq::csv

Commence par remplacer a par `ceil(a)` et b par `floor(b)` et renvoie ensuite les entiers entre les deux, possiblement en décroissant, et extrémités comprises. Si a=b est non entier en obtient donc `ceil(a)` et `floor(a)`. Ne renvoie jamais une liste vide.

Note: le a..b dans `\xintfloatexpr` utilise cette routine.

11.34 ? as two-way and ?? as three-way conditionals with braced branches

In 1.1, I overload ? with ??, as : will be used for list extraction, problem with (stuff)??(1){0} for example, one should put a space (stuff)? ?(1){0} will work. Small idiosyncrasy. (which has been removed in 1.2h, there is no problem anymore with (test)??(1){0}, however (test)??{!}(x) is not accepted; but (test)??(x){!(x)} is or even with ?(?!(x).)

syntax: ?{yes}{no} and ??{<0}{=0}{>0}.

The difficulty is to recognize the second ? without removing braces as would be the case with standard parsing of operators. Hence the ? operator is intercepted in \XINT_expr_getop_b.

1.2h corrects a bug in \XINT_expr_op_? which in context like (test)?{foo}{bar} would provoke expansion of \foo, or also with (test)??{bar} would result in an error. The fix also solves the (test)??(1){0} issue mentioned above.

11.36 The A/B[N] mechanism

Releases earlier than 1.1 required the use of braces around A/B[N] input. The [N] is now implemented directly. *BUT* this uses a delimited macro! thus N is not allowed to be itself an expression (I could add it...). \xintE, \xintiiE, and \XINTinFloatE all put #2 in a \numexpr. But attention to the fact that \numexpr stops at spaces separating digits: \the\numexpr 3 + 7 9\relax gives 109\relax !! Hence we have to be careful.

\numexpr will not handle catcode 11 digits, but adding a \detokenize will suddenly make illicit for N to rely on macro expansion.

11.37 \XINT_expr_op_` for recognizing functions

The "onliteral" intercepts is for bool, togl, protect, ... but also for add, mul, seq, etc... Genuine functions have expr, iiexpr and flexpr versions (or only one or two of the three).

With 1.2c "onliteral" is also used to disambiguate variables from functions. However as I use only a \ifcsname test, in order to be able to re-define a variable as function, I move the check for being a function first. Each variable name now has its onliteral_<name> associated macro which is the new way tacit multiplication in front of a parenthesis is implemented. This used to be decided much earlier at the time of \XINT_expr_func.

The advantage of our choices for 1.2c is that the same name can be used for a variable or a function, the parser will apply the correct interpretation which is decided by the presence or not of an opening parenthesis next.

```

1446         {#1}%
1447 }%
1448 \def\XINT_expr_func_unknown #1#2#3%
1449     {\expandafter #1\expandafter #2\csname .=#0\endcsname }%

```

11.38 The `\bool()`, `\togl()`, `\protect()` pseudo “functions”

`bool`, `togl` and `protect` use delimited macros. They are not true functions, they turn off the parser to gather their “variable”.

```

1450 \def\XINT_expr_onliteral_bool #1)%
1451     {\expandafter\XINT_expr_getop\csname .=#1\endcsname }%
1452 \def\XINT_expr_onliteral_togl #1)%
1453     {\expandafter\XINT_expr_getop\csname .=#1\endcsname }%
1454 \def\XINT_expr_onliteral_protect #1)%
1455     {\expandafter\XINT_expr_getop\csname .=#1\endcsname }%

```

11.39 The `\break()` function

`break` is a true function, the parsing via expansion of the succeeding material proceeded via `_oparen` macros as with any other function.

```

1456 \def\XINT_expr_func_break #1#2#3%
1457     {\expandafter #1\expandafter #2\csname .=?\romannumeral`&&\XINT_expr_unlock #3\endcsname }%
1458 \let\XINT_flexpr_func_break \XINT_expr_func_break
1459 \let\XINT_iiexpr_func_break \XINT_expr_func_break

```

11.40 The `\qraw()`, `\qint()`, `\qfrac()`, and `\qfloat()` “functions”

1.2. adds `qint()`, `qfrac()`, `qfloat()`.

1.3c. adds `qraw()`. Useful to limit impact on TeX memory from abuse of `\csname`'s storage when generating many comma separated values from a loop.

1.3e. `qfloat()` keeps a short mantissa if possible.

They allow the user to hand over quickly a big number to the parser, spaces not immediately removed but should be harmless in general. The `qraw()` does no post-processing at all apart complete

expansion, useful for comma-separated values, but must be obedient to (non really documented) expected format. Each uses a delimited macro, the closing parenthesis can not emerge from expansion.

```

1460 \def\XINT_expr_onliteral_qint #1)%
1461     {\expandafter\XINT_expr_getop\csname .=\xintiNum{#1}\endcsname }%
1462 \def\XINT_expr_onliteral_qfrac #1)%
1463     {\expandafter\XINT_expr_getop\csname .=\xintRaw{#1}\endcsname }%
1464 \def\XINT_expr_onliteral_qfloat #1)%
1465     {\expandafter\XINT_expr_getop\csname .=\XINTinFloatSdigits{#1}\endcsname }%
1466 \def\XINT_expr_onliteral_qraw #1)%
1467     {\expandafter\XINT_expr_getop\csname .=#1\endcsname }%

```

11.41 The `\random()` and `\grand()` “functions”

1.3b. Function-like syntax but with no argument currently, so let's use fast parsing which requires though the closing parenthesis to be explicit.

```

1468 \def\XINT_expr_onliteral_random #1)%
1469     {\expandafter\XINT_expr_getop\csname .=\XINTinRandomFloatSdigits\endcsname }%
1470 \def\XINT_expr_onliteral_grand #1)%
1471     {\expandafter\XINT_expr_getop\csname .=\XINTinRandomFloatSixteen\endcsname }%

```

11.42 `\XINT_expr_op__` for recognizing variables

The 1.1 mechanism for `\XINT_expr_var_<varname>` has been modified in 1.2c. The `<varname>` associated macro is now only expanded once, not twice. We arrive here via `\XINT_expr_func`.

```

1472 \def\XINT_expr_op__ #1% op__ with two '_'s
1473     {%
1474         \ifcsname XINT_expr_var_#1\endcsname
1475             \expandafter\xint_firstoftwo
1476         \else
1477             \expandafter\xint_secondoftwo
1478         \fi
1479         {\expandafter\expandafter\expandafter

1482          \expandafter\XINT_expr_getop\csname .=#1\endcsname}%
1483     }%
1484 \def\XINT_expr_unknown_variable #1{\xintError:removed \xint_gobble_i {#1}}%
1485 \let\XINT_flexpr_op__ \XINT_expr_op__
1486 \let\XINT_iexpr_op__ \XINT_expr_op__

```

11.43 User defined variables: `\xintdefvar`, `\xintdefiivar`, `\xintdeffloatvar`

1.1.

1.2p (2017/12/01). extends `\xintdefvar` et al. to accept simultaneous assignments to multiple variables.

1.3c (2018/06/17). Use `\xintexprSafeCatcodes` (to palliate issue with active semi-colon from Babel+French if in body of a \TeX document).

And allow usage with both syntaxes `name:=expr`; or `name=expr`; . Also the colon may have catcode 11, 12, or 13 with no issue. Variable names may contain letters, digits, underscores, and must not start with a digit. Names starting with @ or an underscore are reserved.

- currently @, @1, @2, @3, and @4 are reserved because they have special meanings for use in iterations,
- @@, @@@, @@@@ are also reserved but are technically functions, not variables: a user may possibly define @@ as a variable name, but if it is followed by parentheses, the function interpretation will be applied (rather than the variable interpretation followed by a tacit multiplication),
- since 1.21, the underscore _ may be used as separator of digits in long numbers. Hence a variable whose name starts with _ will not play well with the mechanism of tacit multiplication of variables by numbers: the underscore will be removed from input stream by the number scanner, thus creating an undefined or wrong variable name, or none at all if the variable name was an initial _ followed by digits.

```

11.45 seq and the implementation of dummy variables

11.45.1	All letters usable as dummy variables, <code>\xintnewdummy</code>	339
11.45.2	<code>xintensuredummy</code> , <code>xintrestorelettervar</code>	340
11.45.3	<code>\omit()</code> and <code>\abort()</code>	341
11.45.4	The special variables <code>@</code> , <code>@1</code> , <code>@2</code> , <code>@3</code> , <code>@4</code> , <code>@@</code> , <code>@@(1)</code> , . . . , <code>@@@</code> , <code>@@@(1)</code> , . . . for recursion	342
11.45.5	<code>\XINT_expr_onliteral_seq</code>	343
11.45.6	<code>\XINT_expr_onliteral_seq_a</code>	343
11.45.7	<code>\XINT_isbalanced_a</code> for <code>\XINT_expr_onliteral_seq_a</code>	343
11.45.8	<code>\XINT_allexpr_func_seqx</code>	344
11.45.9	Evaluation over list, <code>\XINT_expr_seq:_a</code> with break, abort, omit	344
11.45.10	Evaluation over ++ generated lists with <code>\XINT_expr_seq:_A</code>	345

All of seq, add, mul, rseq, etc... (actually all of the extensive changes from xintexpr 1.09n to 1.1) was done around June 15-25th 2014, but the problem is that I did not document the code enough, and I had a hard time understanding in October what I had done in June. Despite the lesson, again being short on time, I do not document enough my current understanding of the innards of the beast...

I added subs, and iter in October (also the [:n], [n:] list extractors), proving I did at least understand a bit (or rather could imitate) my earlier code (but don't ask me to explain `\xintNewExpr` !)

The `\XINT_expr_onliteral_seq_a` parses: "expression, variable=list)" (when it is called the opening (has been swallowed, and it looks for the ending one.) Both expression and list may themselves contain parentheses and commas, we allow nesting. For example "x^2,x=1..10)", at the end of seq_a we have {variable{expression}}{list}, in this example {x{x^2}}{1..10}, or more complicated "seq(add(y,y=1..x),x=1..10)" will work too. The variable is a single lowercase Latin letter.

The complications with `\xint_c_xviii` in seq_f is for the recurrent thing that we don't know in what type of expressions we are, hence we must move back up, with some loss of efficiency (superfluous check for minus sign, etc...). But the code manages simultaneously expr, flexpr and iiexpr.

11.45.1 All letters usable as dummy variables, `\xintnewdummy`

The nil variable was introduced in 1.1 but isn't used under that name. However macros handling a..[d]..b, or for seq with dummy variable where omit has omitted everything may in practice inject a nil value as current number.

1.2c has changed the way variables are disambiguated from functions and for this it has added here the definitions of `\XINT_expr_onliteral_<name>`.

In 1.1 a letter variable say X was acting as a delimited macro looking for `!X{stuff}` and then would expand the stuff inside a `\csname.=...\endcsname`. I don't think I used the possibilities

this opened and the 1.2c version has stuff `_already_` encapsulated thus a single token. Only one expansion, not two is then needed in `\XINT_expr_op__`.

I had to accordingly modify `seq`, `add`, `mul` and `subs`, but fortunately realized that the `@`, `@1`, etc... variables for `rseq`, `rrseq` and `iter` already had been defined in the way now also followed by the Latin letters as dummy variables.

The 1.2e `\XINT_expr_makedummy` was adjoined `\xintnewdummy` by 1.2k for a public interface. It should not be used with multi-letter argument. The `add`, `mul`, `seq`, etc... can only work with one-letter long dummy variable. And this will almost certainly not change.

Also 1.2e does the tacit multiplication `x(stuff)->x*(stuff)` in its higher precedence form. Things are easy now that variables always fetch a single already locked value `\.<number>`.

The tacit multiplication in case of the `'`nil'` variable doesn't make much sense but we do it anyhow.

1.3e stores earlier meaning for usage by `xinttrig` and `xintlog` with `\xintensuredummy` and `\xintrestoredummy` as high-level interface.

Do an `\xintrestorevar`, and patch `\xintdefvar` to always store previous meaning?

11.45.3 `\omit()` and `\abort()`

June 24 and 25, 2014.

Added comments 2015/11/13:

Et la documentation ? on n'y comprend plus rien. Trop rusé.

```

\def\XINT_expr_var_omit #1\relax !{1^C!}{}}{}}\.\!=!\relax !}
\def\XINT_expr_var_abort #1\relax !{1^C!}{}}{}}\.\!=^\relax !}
```

C'était accompagné de `\XINT_expr_precedence_^C=0` et d'un hack au sein même des macros until de plus bas niveau.

Le mécanisme sioux était le suivant: `^C` est déclaré comme un opérateur de précedence nulle. Lorsque le parseur trouve un "omit" dans un seq ou autre, il va insérer dans le stream `\XINT_expr_getop` suivi du texte de remplacement. Donc ici on avait un 1 comme place holder, puis l'opérateur `^C`. Celui-ci étant de précedence zéro provoque la finalisation de tous les calculs antérieurs dans le sous-bareeval. Mais j'ai dû hacker le `until_end_b` (et le `until_)_b`) qui confronté à `^C`, va se relancer à zéro, le `getnext` va trouver le `!{}{}{}}\.\!=!` et ensuite il y aura `\relax`, et le résultat sera `\.\!=!` pour `omit` ou `\.\!=^` pour `abort`. Les routines des boucles `seq`, `iter`, etc... peuvent alors repérer le `!` ou `^` et agir en conséquence (un long paragraphe pour ne décrire que partiellement une ou deux lignes de codes...).

Mais `^C` a été fait alors que je n'avais pas encore les variables muettes. Je dois trouver autre chose, car `seq(2^C, C=1..5)` est alors impossible. De toute façon ce `^C` était à usage interne uniquement.

Il me faut un symbole d'opérateur qui ne rentre pas en conflit. Bon je vais prendre `!?`. Ensuite au lieu de hacker `until_end`, il vaut mieux lui donner précedence 2 (mais ça ne pourra pas marcher à l'intérieur de parenthèses il faut d'abord les fermer manuellement) et lui associer un simplement

un op spécial. Je n'avais pas fait cela peut-être pour éviter d'avoir à définir plusieurs macros. Le #1 dans la définition de \XINT_expr_op_!? est le résultat de l'évaluation forcée précédente.

Attention que les premier ! doivent être de catcode 12 sinon ils signalent une sous-expression qui déclenche une multiplication tacite.

```
1632 \edef\XINT_expr_var_omit #1\relax !{\string !?!\relax !}%
1633 \edef\XINT_expr_var_abort #1\relax !{\string !?^\relax !}%
1634 \def\XINT_expr_op_!? #1#2\relax {\expandafter\XINT_expr_founded\csname .=#2\endcsname}%
1635 \let\XINT_iiexpr_op_!? \XINT_expr_op_!?
1636 \let\XINT_flexpr_op_!? \XINT_expr_op_!?
```

11.45.4 The special variables @, @1, @2, @3, @4, @@, @@(1), ..., @@@, @@@(1), ... for recursion

October 2014: I had completely forgotten what the @@@ etc... stuff were supposed to do: this is for nesting recursions! (I was mad back in June). @@(N) gives the Nth back, @@@(N) gives the Nth back of the higher recursion!

1.2c adds the needed "onliteral" now that tacit multiplication between a variable and a (has a new mechanism. 1.2e does this tacit multiplication with higher precedence.

For the record, the ~ has catcode 3 in this code.

11.45.8 \XINT_allexpr_func_seqx

1.2c uses \xintthebareval, ... which strangely were not available at 1.1 time. This spares some tokens from \XINT_expr_seq:_d and cousins. Also now variables have changed their mode of operation they pick only one token which must be an already encapsulated value.

In \XINT_allexp_seqx, #2 is the list, evaluated and encapsulated, #3 is the dummy variable, #4 is the expression to evaluate repeatedly.

A special case is a list generated by <variable>+: then #2 is {\.=+\.=<start>}

```

1722 \def\XINT_expr_func_seqx #1#2{\XINT_allexpr_seqx \xintthebareval }%

```

11.45.9 Evaluation over list, \XINT_expr_seq:_a with break, abort, omit

The #2 here is \...bareeval <expression>\relax !<variable name>. The #1 is a comma separated list of values to assign to the dummy variable. The \XINT_expr_seq_empty? intervenes immediately after handling of firstvalue.

1.2c has rewritten to a large extent this and other similar loops because the dummy variables now fetch a single encapsulated token (apart from a good means to lose a few hours needlessly -- as I have had to rewrite and review most everything, this change could make the thing more efficient

if the same variable is used many times in an expression, but we are talking micro-seconds here anyhow.)

```

1733 \def\XINT_expr_seq:_a #1!#2{\expandafter\XINT_expr_seq_empty?

```

11.45.10 Evaluation over ++ generated lists with `\XINT_expr_seq:_A`

This is for index lists generated by `n++`. The starting point will have been replaced by its ceil (added: in fact with version 1.1. the ceil was not yet evaluated, but `_var_<letter>` did an expansion of what they fetch). We use `\numexpr` rather than `\xintInc`, hence the indexing is limited to small integers.

The 1.2c version of `n++` produces a `#1` here which is already a single `\.<value>` token.

```

1754 \def\XINT_expr_seq:_A ++#1!%
1755     {\expandafter\XINT_expr_seq_empty?\romannumeral0\XINT_expr_seq:_D #1}%

11.48 \rseq()

11.48.1 \XINT_expr_rseqx	347
11.48.2 \XINT_expr_rseqy	348
11.48.3 \XINT_expr_rseq:_a etc.	348
11.48.4 \XINT_expr_rseq:_A etc.	348

When func_rseq has its turn, initial segment has been scanned by oparen, the ; mimicking the rôle of a closing parenthesis, and stopping further expansion. Notice that the ; is discovered during standard parsing mode, it may be for example {;} or arise from expansion as rseq does not use a delimited macro to locate it.

Here and in rrseq and iter, 1.2c adds also use of \xintthebareeval, etc. . . .

```

11.49 \iter()

11.49.1	\XINT_expr_iterx	349
11.49.2	\XINT_expr_itery	349
11.49.3	\XINT_expr_iter:_a etc...	350
11.49.4	\XINT_expr_iter:_A etc...	350

Prior to 1.2g, the iter keyword was what is now called iterr, analogous with rrseq. Somehow I forgot an iter functioning like rseq with the sole difference of printing only the last iteration. Both rseq and iter work well with list selectors, as @ refers to the whole comma separated sequence of the initial values. I have thus deliberately done the backwards incompatible renaming of iter to iterr, and the new iter.

11.52 Macros handling csv lists for functions with multiple comma separated arguments in expressions

11.52.1	\xintANDof:csv	355
11.52.2	\xintORof:csv	355
11.52.3	\xintXORof:csv	355
11.52.4	Generic csv routine (\XINT_oncsv:_a)	355
11.52.5	\xintMaxof:csv, \xintiiMaxof:csv	356
11.52.6	\xintMinof:csv, \xintiiMinof:csv	356
11.52.7	\xintSum:csv, \xintiiSum:csv	356
11.52.8	\xintPrd:csv, \xintiiPrd:csv	356
11.52.9	\xintGCDof:csv, \xintLCMof:csv	356
11.52.10	\xintiiGCDof:csv, \xintiiLCMof:csv	358
11.52.11	\XINTinFloatdigits, \XINTinFloatSqrtdigits, \XINTinFloatFacdigits, \XINTiLog-Tendigits	358
11.52.12	\XINTinFloatMaxof:csv, \XINTinFloatMinof:csv	358
11.52.13	\XINTinFloatSum:csv, \XINTinFloatPrd:csv	359

These macros are used inside \csname...\endcsname. These things are not initiated by a \romannumeral in general, but in some cases they are, especially when involved in an \xintNewExpr. They will then be protected against expansion and expand only later in contexts governed by an initial \romannumeral-`0. There each new item may need to be expanded, which would not be the case in the use for the _func_ things.

1.2g adds (to be continued)

11.52.1 \xintANDof:csv

1.09a. For use by \xintexpr inside \csname. 1.1, je remplace ifTrueAelseB par iiNotZero pour des raisons d'optimisations.

```
2065 \def\xintANDof:csv #1{\expandafter\XINT_andof:_a\romannumeral`&&@#1,,^}%
2066 \def\XINT_andof:_a #1{\if ,#1\expandafter\XINT_andof:_e
2067         \else\expandafter\XINT_andof:_c\fi #1}%
2068 \def\XINT_andof:_c #1,{\xintiifNotZero {#1}{\XINT_andof:_a}{\XINT_andof:_no}}%
2069 \def\XINT_andof:_no #1^{0}%
2070 \def\XINT_andof:_e #1^{1}% works with empty list
```

11.52.2 \xintORof:csv

1.09a. For use by \xintexpr.

```
2071 \def\xintORof:csv #1{\expandafter\XINT_orof:_a\romannumeral`&&@#1,,^}%
2072 \def\XINT_orof:_a #1{\if ,#1\expandafter\XINT_orof:_e

```

11.52.5 `\xintMaxof:csv`, `\xintiiMaxof:csv`

1.09i. Rewritten for 1.1. Compatible avec liste vide donnant valeur par défaut. Pas compatible avec items manquants. ah je m'aperçois au dernier moment que je n'ai pas en effet de `\xintiiMax`. Je devrais le rajouter. En tout cas ici c'est uniquement pour `xintiexpr`, dans il faut bien sûr ne pas faire de `xintNum`, donc il faut un `iimax`.

```
2098 \def\xintMaxof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintmax
2099   \expandafter\xint_firstofone\romannumeral`&&@#1,^,{0/1[0]}}%
2100 \def\xintiiMaxof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintiiimax
2101   \expandafter\xint_firstofone\romannumeral`&&@#1,^,0}%
```

11.52.6 `\xintMinof:csv`, `\xintiiMinof:csv`

1.09i. Rewritten for 1.1. For use by `\xintiexpr`.

```
2102 \def\xintMinof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintmin
2103   \expandafter\xint_firstofone\romannumeral`&&@#1,^,{0/1[0]}}%
2104 \def\xintiiMinof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintiiimin
2105   \expandafter\xint_firstofone\romannumeral`&&@#1,^,0}%
```

11.52.7 `\xintSum:csv`, `\xintiiSum:csv`

1.09a. Rewritten for 1.1. For use by `\xintexpr`.

```
2106 \def\xintSum:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintadd
2107   \expandafter\xint_firstofone\romannumeral`&&@#1,^,{0/1[0]}}%
2108 \def\xintiiSum:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintiiadd
2109   \expandafter\xint_firstofone\romannumeral`&&@#1,^,0}%
```

11.52.8 `\xintPrd:csv`, `\xintiiPrd:csv`

1.09a. Rewritten for 1.1. For use by `\xintexpr`.

```
2110 \def\xintPrd:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintmul
2111   \expandafter\xint_firstofone\romannumeral`&&@#1,^,{1/1[0]}}%
2112 \def\xintiiPrd:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintiiimul
2113   \expandafter\xint_firstofone\romannumeral`&&@#1,^,1}%
```

11.52.9 `\xintGCDof:csv`, `\xintLCMof:csv`

1.09a. Non-integer arguments are replaced by integers as `\xintGCD` and `\xintLCM` apply `\xintNum`.

1.1. As with other "csv" macros, the (list) argument needs to be expanded in case it arises within a macro created from `\xintNewExpr`.

1.3d. No more usage of the integer-only `xintgcd` macros, replaced by direct coding here, in order to extend scope to fractions (and produce fractions). Hesitation about allowing empty input, and what to return then.

```
2114 \def\xintGCDof:csv #1{\expandafter\XINT_gcdof:_a\romannumeral`&&@#1,^,{1/1[0]}}%
2115 \def\XINT_gcdof:_a #1%
2116   {\if ,#1\expandafter\XINT_onscv:_empty\else\expandafter\XINT_gcdof:_b\fi #1}%
```

This abuses the way `\xintiiabs` works in order to avoid fetching whole argument again.

```
2117 \def\xINT_gcdof:_b #1,%
2118   {\expandafter\xINT_gcdof:_c\romannumeral0\xintiiabs#1\xint:}%
2119 \def\xINT_gcdof:_c #1\xint:#2,%
2120   {\expandafter\xINT_gcdof:_d\romannumeral0\xintiiabs#2\xint:#1\xint:}%
2121 \def\xINT_gcdof:_d #1%
2122   {\if ^#1\expandafter\xINT_gcdof:_end\else\expandafter\xINT_gcdof:_e\fi #1}%
```

`\xintMod` will apply `\xintRaw` on its arguments, and will output in normalized format. But in exceptional case with a one-item or one item and then zeros, the output is (absolute value of this item, not necessarily in A/B[N] format).

```
2123 \def\xINT_gcdof:_e#1#2\xint:#3\xint:
2124 {%
2125   \if0#1\expandafter\xINT_gcdof:_f\fi
2126   \expandafter\xINT_gcdof:_e\romannumeral0\xintmod{#3}{#1#2}\xint:#1#2\xint:
2127 }%
2128 \def\xINT_gcdof:_f
2129   \expandafter\xINT_gcdof:_e\romannumeral0\xintmod#1#2\xint:#3\xint:#4,%
2130 {%
2131   \expandafter\xINT_gcdof:_d\romannumeral0\xintiiabs#4\xint:#1\xint:
2132 }%
```

As for others :csv macros here expansion in the case of `\xintNewExpr` crafted macros is triggered by (an equivalent to) `\romannumeral-`0`. Else it happens inside `\csname...\endcsname`, and there is no triggering `\romannumeral`, attention to not leave a space upfront.

```
2133 \def\xINT_gcdof:_end ^\xint:#1\xint:#2{#1}%
```

For least common multiple, we will use `\xintInv`, but this requires to make sure fractional input is in raw format.

```
2134 \def\xintLCMof:csv #1{\expandafter\xINT_lcmof:_a\romannumeral`&&@#1,^,{0/1[0]}}%
2135 \def\xINT_lcmof:_a #1%
2136   {\if ,#1\expandafter\xINT_oncsv:_empty\else\expandafter\xINT_lcmof:_b\fi #1}%
2137 \def\xINT_lcmof:_b #1,%
2138   {\expandafter\xINT_lcmof:_c\romannumeral0\xintiiabs\xintRaw{#1}\xint:}%
2139 \def\xINT_lcmof:_c #1{\if0#1\expandafter\xINT_lcmof:_zero\fi
2140   \expandafter\xINT_lcmof:_d\romannumeral0\xINT_inv #1}%
```

We can do `\xintiiabs^`, but `\xintiiabs\xintRaw{^}` would throw an error. So we need to delay applying `\xintRaw` to new item.

```
2141 \def\xINT_lcmof:_d #1\xint:#2,%
2142   {\expandafter\xINT_lcmof:_e\romannumeral0\xintiiabs#2\xint:#1\xint:}%
2143 \def\xINT_lcmof:_e #1%
2144   {\if ^#1\expandafter\xINT_lcmof:_end\else\expandafter\xINT_lcmof:_f\fi #1}%
```

As soon as we hit against a zero item, the l.c.m is known to be zero itself. Else we need to inverse it, but this requires full A/B[N] raw format, hence the `\xintraw`.

```
2145 \def\xINT_lcmof:_f#1#2\xint:
2146 {%
2147   \if0#1\expandafter\xINT_lcmof:_zero\fi
2148   \expandafter\xINT_lcmof:_g\romannumeral0\expandafter\xINT_inv
```

```

2149 \romannumeral0\xintra{#1#2}\xint:
2150 }%
2151 \def\XINT_lcmof:_g #1#2\xint:#3\xint:

2160 }%
2161 \def\XINT_lcmof:_zero #1^,#2{0/1[0]}%

```

We need this `\romannumeral0` to remove the up-front space token which will be left by `\XINT_inv`, in case of `\csname.. \endcsname` expansion.

```

2162 \def\XINT_lcmof:_end ^\xint:#1\xint:#2{\romannumeral0\XINT_inv #1}%

```

11.52.10 `\xintiiGCDof:csv`, `\xintiiLCMof:csv`

1.1a. For `\xintiiexpr`. Requires the `xintgcd` provided macros.

```

2163 \def\xintiiGCDof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintiigcd
2164 \expandafter\xint_firstofone\romannumeral`&&@#1,^,1}%
2165 \def\xintiiLCMof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintii lcm
2166 \expandafter\xint_firstofone\romannumeral`&&@#1,^,0}%

```

11.52.11 `\XINTinFloatdigits`, `\XINTinFloatSqrtdigits`, `\XINTinFloatFacdigits`, `\XINTiLogTendigits`

For `\xintNewExpr` matters, mainly.

At 1.3e I add `\XINTinFloatSdigits` and use it at various places. I also modified `\XINTinFloatFac` to use `S(hort)` output format.

Also added `\XINTiLogTendigits`

```

2167 \def\XINTinFloatdigits {\XINTinFloat [\XINTdigits]}%
2168 \def\XINTinFloatSdigits {\XINTinFloatS [\XINTdigits]}%
2169 \def\XINTinFloatSqrtdigits {\XINTinFloatSqrt[\XINTdigits]}%
2170 \def\XINTinFloatFacdigits {\XINTinFloatFac [\XINTdigits]}%
2171 \def\XINTFloatiLogTendigits{\XINTFloatiLogTen[\XINTdigits]}%

```

11.52.12 `\XINTinFloatMaxof:csv`, `\XINTinFloatMinof:csv`

1.09a. Rewritten for 1.1. For use by `\xintfloatexpr`. Name changed in 1.09h. Changed at 1.3e to use `\XINTinFloatSdigits`.

```

2172 \def\XINTinFloatMaxof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintmax
2173 \expandafter\XINTinFloatSdigits\romannumeral`&&@#1,^,{0[0]}}%
2174 \def\XINTinFloatMinof:csv #1{\expandafter\XINT_onscv:_a\expandafter\xintmin
2175 \expandafter\XINTinFloatSdigits\romannumeral`&&@#1,^,{0[0]}}%

```

11.52.13 \XINTinFloatSum:csv, \XINTinFloatPrd:csv

1.09a. Rewritten for 1.1. For use by \xintfloatexpr. Modified at 1.3e to use \XINTinFloatSdigits.

```
2176 \def\XINTinFloatSum:csv #1{\expandafter\XINT_oncsv:_a\expandafter\XINTinfloatadd
2177         \expandafter\XINTinFloatSdigits\romannumeral`&&@#1,^{0[0]}}%

1.2c I hesitated but left the function "reversed" from 1.1 with this name, not "reverse". But the inner not public macro got renamed into \xintReverse::csv. 1.2g opts for the name \xintReverse:f:csv, and rewrites it for direct handling of csv lists. 2016/03/17.

11.55.2 \xintiiSeqB:f:csv

Produces in f-expandable way. If the step is zero, gives empty result except if start and end coincide.

2015/11/11. I correct a typo dating back to release 1.1 (2014/10/29): the macro name had a "b" rather than "B", hence was not functional (causing \xintNewIIExpr to fail on inputs such as #1..[1]..#2).

11.56 \xintdeffunc, \xintdefiifunc, \xintdeffloatfunc

1.2c (2015/11/12).

Note: it is possible to have same name assigned both to a variable and a function: things such as add(f(f), f=1..10) are possible.

1.2f (2016/03/08).

Comma separated expressions allowed (formerly this required using parenthesis \xintdeffunc foo(x,..):=(.., .., ..));

1.3c (2018/06/17).

Usage of `\xintexprSafeCatcodes` to be compatible with an active semi-colon at time of use; the colon was not a problem (see ##3) already.

```

```

We try to distinguish wheter the function is supposed to deliver only one value or more than two. And we separate the cases of 0, 1 or 2 variables which can be set-up a bit better for usage in other definitions, in generator environments. But there are many shortcomings. I don't have a very clear view of all the complex situation, in fact.

Le fait que `\xintExpandArgs` demande que les arguments sont regroupés explique pourquoi plus bas j'ai dû faire `\XINT:NE:userefunc:two`.

```
\xintExpandArgs#1{##1}{##2}}
```

Mais bon finalement je rajouter encore un helper d'expansion. Que j'ai peut-être d'ailleurs déjà... C'est un peu de l'abus la macro auxiliaire `userefunc:f` pour chaque `userefunc`, mais je dois gérer le problème que les noms de macros ici peuvent contenir des chiffres.

Il y a de la perte dans le grabbing de l'argument qui aura lieu et qu'on pourrait optimiser, mais je commence à sérieusement fatiguer pour 1.3e.

11.60 `\xintNewExpr`, `\xintNewIExpr`, `\xintNewFloatExpr`, `\xintNewIIExpr`

11.60.1	<code>\xintApply::csv</code> and <code>\xintApply:::csv</code>	381
11.60.2	Mysterious stuff	381
11.60.3	<code>\XINT_expr_redefinemacros</code>	386
11.60.4	<code>\XINT_expr_redefineprints</code>	387
11.60.5	<code>\xintNewExpr</code> , ..., at last.	387
11.60.6	<code>\ifxintexprsafecatcodes</code> , <code>\xintexprSafeCatcodes</code> , <code>\xintexprRestoreCatcodes</code> . .	389

There was an `\xintNewExpr` already in 1.07 from May 2013, which was modified in September 2013 to work with the `#` macro parameter character, and then refactored into a more powerful version in June 2014 for 1.1 release of 2014/10/28. List handling causes special challenges, addressed by `\xintApply::csv`, `\xintApply:::csv`, ... next.

Comments finally added 2015/12/11 (with later edits):

The whole point is to expand completely macros when they have only numerical arguments and to inhibit this expansion if not. This is done in a recursive way: the catcode `12 ~` is used to register a macro name whose expansion must be inhibited. Any argument itself starting with such a `~` will force use of `~` for the macro which receives it.

In this context the catcode `12 $` is used to signal a "virtual list" argument. It triggers insertion of `\xintApply::csv` or `\xintApply:::csv` for delayed handling later. This succeeds into handling inputs such as `[#1..[#2]..#3][#4:#5]...`

A final `\scantokens` converts the `"~"` prefixed names into real control sequences.

For this whole mechanism we need to have everything expressed using exclusively f-expandable macros. We avoid `\csname... \endcsname` like construct, but if absolutely needed perhaps we will do it ultimately.

For the iterating loops `seq`, `iter`, etc..., and dummy variables, we have no macros to our disposal to handle the case where the list of indices is not explicit. Moreover `omit`, `abort`, `break` can not work with non numerical data. Thus the whole mechanism is currently not applicable to them. It does work when the macro parameters (or variables for `\xintdeffunc`) do not intervene in the list of values to iterate over. But we can not delay expansion of dummy variables.

Comments added 2018/02/28:

At 1.3 of February 2018, there was important refactoring. Earlier, `\XINT_expr_redefinemacros` was a very big macro which made aliases of the dozens of macros (most from `xintfrac` and some defined especially by `xintexpr` for acting on `csv` lists primarily) involved in the expression rendering and then redefined them all to expand to their original selves only when applied to purely numeric arguments. At 1.3 only very few such re-definitions are made, as what is redefined are a limited number of core wrapper macros.

Only when the original macros have one or two arguments is it examined if they can expand immediately (this includes case of function having possibly only one, or possibly two arguments). For macros applying to three or more or an undefined number of arguments, we don't complicate matters into checking if expansion is possible, and we delay that expansion automatically (but `if()` and `ifsgn()` do check if first argument is numeric and expand to suitable branch in that case).

In particular any function defined by `\xintdeffunc` or `\xintNewFunction` (it is then basically only a macro abstraction) when used in new function definitions will never be expanded immedi-

ately, because the detection of whether they are applied to only numerical data has not yet been added. (this might be added in future).

Some aspects of the 1.3 refactoring have made recursive definition via `\xintdeffunc` possible (of course they always were via `\xintNewFunction` as the latter is but a wrapper of a standard TeX macro definition, where `\xintexpr` parsing is not at all involved).

A somewhat complicated layer (not modified at 1.3) is devoted to making possible the parsing of constructs such as `[#1..[#2]..#3][#4:#5]` or `[#1..#2]*#3` and it seems to work. At 1.3, even esoteric construct such as `[divmod(#1,#2)]*#3` is parsable by `\xintNewExpr`. (In `\xintNewFloatExpr`, don't forget `\empty` token so that square brackets are not mistaken for optional argument of `\xintthefloatexpr`; same for `\xintdeffloatfunc`.)

Side note: I wonder if I really had a good idea to define these list operations `[..]*foo` or `foo^[...]` which do not seem to occur in other languages with the meanings I used. And they caused me lots of efforts for support at `\xintNewExpr` level...

The catcode 12 dollar sign is used to signal when a macro can not be expanded but would produce a csv list. Furthermore some cases require f-expandable macros as the original code expanding in `\xintexpr` is in `\csname` context and did not need f-expandability.

As mentioned above, currently syntax with dummy variables can not go through where the values iterated over are not explicit; and omit, abort, break mechanisms are not parsable with non purely numerical data, in part because they are not implemented internally via pure f-expansion.

11.60.1 `\xintApply::csv` and `\xintApply:::csv`

Serve in particular to support things such as

```
\xintdeffunc foo(x):=seq(sqr(i), i=0..x);
```

... as far as I still understand what is going on here! The most complicated is for list operations; many things involving sequences don't go through `\xintNewExpr`, especially with functions of more than one variable.

```

```

\XINT:NE:userefunc et al. added at 1.3e. For one and two I can not use \XINT:NE:one due to possible digits in names. For more than two nothing special done with mysterious "Apply" macros above.

Should they ever use in output? Je crois que j'ai des problèmes en particulier car j'utilise le most liste dans plusieurs sens il y a en particulier la confusion possible pour liste dans le sens restreint devant être géré par les opérations genre]* ou celui avec les seq() ou finalement la liste des arguments d'une fonction.

When expansion of the user func can not happen on the spot, the version which will be expanded later one must first expand its argument for efficiency because the functions from \XINT_NewFunc do not do that and we must thus have an auxiliary variant expanding its argument.

```

```

11.60.4 `\XINT_expr_redefineprints`

This was used by `\xintNewExpr` but not by `\xintdeffunc` until 1.3e. Since then, used by both.

Comma separated sub-expressions are not supported, the expansion is inhibited but it is not checked if it would have given strictly more than one value.

```

11.60.5 `\xintNewExpr`, ..., at last.

1.2c modifications to accomodate `\XINT_expr_deffunc_newexpr` etc..

1.2f adds token `\XINT_newexpr_clean` to be able to have a different `\XINT_newfunc_clean`.

As `\XINT_NewExpr` always execute `\XINT_expr_redefineprints` since 1.3e whether with `\xintNewExpr` or `\XINT_NewFunc`, it has been moved from argument to hardcoded in replacement text.

```

3433 \def\xintNewExpr      {\XINT_NewExpr\xint_firstofone

```

1.2c adds optional logging. For this needed to pass to _NewExpr_a the macro name as parameter. Up to and including 1.2c the definition was global. Starting with 1.2d it is done locally. Modified at 1.3c so that \XINT_NewFunc et al. do not execute the \xintexprSafeCatcodes, as it is now already done earlier by \xintdeffunc. Modified at 1.3e: \XINT_NewFunc et al. do issue \XINT_expr_redefineprints. I suppose I did not use it formely as I considered it unneeded overhead, but this meant that \xintdeffunc foo(x):=\xintfloatexpr bar(x)\relax; was impossible. But such a syntax is convenient for xinttrig.sty to transfer float functions to normal functions.

1.2d's \xintNewExpr makes a local definition. In earlier releases, the definition was global. \the\toks0 inserts the \endgroup, but this will happen after \XINT_tmpa has already been expanded... The %1 is \xint_firstofone for \xintNewExpr, \xint_gobble_i for \xintdeffunc. The ~ action was modified at 1.3e for ~! constructs (userefunc:f macros).

12.18	Synonyms: <code>tg()</code> , <code>cotg()</code>	406
12.19	Let the functions be known to the <code>\xintexpr</code> parser	406

The original was done in January 15 and 16, 2019. It provided `asin()` and `acos()` based on a Newton algorithm approach. Then during March 25-31 I revisited the code, adding more inverse trigonometrical functions (with a modified algorithm, quintically convergent), extending the precision range (so that the package reacts to the `\xintDigits` value at time of load, or reload), and replaced high level range reduction by some optimized lower level coding.

This led me next to improve upon the innards of `\xintdeffunc` and `\xintNewExpr`, and to add to `xintexpr` the `\xintdefefunc` macro (see user documentation).

Finally on April 5, 2019 I pushed further the idea of the algorithm for the arcsine function. The cost is at least the one of a combined `sin()/cos()` evaluation, surely this is not best approach for low precision, but I like the principle and its suitability to go into hundreds of digits if desired.

Almost all of the code remains written at high level, and in particular it is not easily feasible from this interface to execute computations with guard digits. Expect the last one or two digits to be systematically off.

Also, small floating-point inputs are handled quite sub-optimally both for the direct and inverse functions; substantial gains are possible. I added the `ilog10()` function too late to consider using it here with the high level interface.

12.5 Auxiliary variables (only temporarily needed, but left free to re-use)

These variables don't have really private names but this does not matter because only their actual values will be stored in the functions defined next. Nevertheless they are not unassigned, and are left free to use as is.

12.5.1 twoPi, threePiover2, Pi, Piover2

We take them with 60 digits and force conversion to \xintDigits setting via "0 + " syntax.

```
55 \xintdeffloatvar twoPi      := 0 +
56   6.28318530717958647692528676655900576839433879875021164194989;%

```

12.5.3 Inverse factorial coefficients: invfact2, ..., invfact44

Pre-compute $1/n!$ for $n = 2, \dots, 44$

The following example (among many, see below) shows that we must be careful when pre-computing the $1/i!$.

Consider $35!=10333147966386144929666651337523200000000$.

With `\xintDigit:=26; \xintfloateval{35!}` obtains $1.0333147966386144929666651e40$ which is the correct rounding to 26 digits. But `\xintfloateval{1/35!}` obtains $9.6775929586318909920898167e-41$ which differs by 3ulps from the correct rounding of $1/35!$ to 26 places which is $9.6775929586318909920898164e-41$. The problem isn't in the factorial computations, but in the fact that the rounding of the inverse of a quantity which is itself a rounding is not necessarily the rounding of the exact inverse of the original.

Here is a little program to explore this phenomenon systematically:

```
\xintDigits:=55;%
\edef\tempNlist{\xintSeq{2}{39}}
\xintFor*#1in{\tempNlist}\do{% we precompute some rounding here to
```

```

% speed up things in the next double loop.
\expandafter\edef\csname invfact#1\endcsname {\xintfloatexpr 1/#1!\relax}%
}%
\xintFor*#1in{\xintSeq{4}{50}}\do{%
  \xintDigits:=#1;%
  \xintFor*#2in{\tempNlist}\do{%
    (D=#1, N=#2)
    % attention to != which is parsed as negation operator != followed by = (sigh...)
    \xintifboolfloatexpr{(1/#2!)==0+\csname invfact#2\endcsname}%
    {ok}
    {mismatch: \xintfloateval{1/#2!} vs (exact)
      \xintfloateval{0+\csname invfact#2\endcsname}}%
  \par
}%
}%

```

We can see that for D=16, the problem is there with N=22, 25, 26, 27, 28...and more. If we were to use 1/i! directly in the `\xintdeffloatefunc` of `sin_aux(X)` and `cos_aux(X)` we would have this problem.

If we use `\xintexpr1/i!\relax` encapsulation in the function declaration the rounding will be delayed to actual use of the function... which is bad, so we need it to happen now. We could use `(0+\xintexpr1/i!\relax)` inside the declaration of the sine and cosine series, which will give the expected result but for readability we use some temporary variables. We could use `seq(0+\xintexpr1/i!\relax, i = 2..44)` but opt for an `rseq`. The semi-colon must be braced to hide it from `\xintdeffloatvar` grabbing of the delimited argument.

```

67 \xintdeffloatvar invfact\xintListWithSep{, invfact}{\xintSeq{2}{44}}%
68 := seq(0+x, x=\xintexpr rseq(1/2{;}@/i, i=3..44)\relax);% need to hide inner ;

```

12.6 The sine and cosine series

12.6.1 `sin_aux()`, `cos_aux()`

Should I rather use successive divisions by $(2n+1)(2n)$, or rather multiplication by their pre-computed inverses, in a modified Horner scheme? The `\ifnum` tests are executed at time of definition.

Criteria for truncated series using $\pi/4$, actually 0.79.

Small values of the variable X are very badly handled here because a much shorter truncation of the sine series should be used.

```

69 \xintdeffloatefunc sin_aux(X) := 1 - X(invfact3 - X(invfact5
70 \ifnum\XINTdigits>4
71 - X(invfact7
72 \ifnum\XINTdigits>6
73 - X(invfact9
74 \ifnum\XINTdigits>8
75 - X(invfact11
76 \ifnum\XINTdigits>10
77 - X(invfact13
78 \ifnum\XINTdigits>13
79 - X(invfact15
80 \ifnum\XINTdigits>15
81 - X(invfact17
82 \ifnum\XINTdigits>18
83 - X(invfact19

```

12.7.1 Core level macro \XINT_mod_ccclx_i

input: \the\numexpr\XINT_mod_ccclx_i k.N. (delimited by dots)

output: (N times 10^k) modulo 360. (with a final dot)

Attention N must be non-negative (I could make it accept negative but the fact that numexpr / is not periodical in numerator adds overhead).

360 divides 9000 hence 10^k is 280 for k at least 3 and the additive group generated by it modulo 360 is the set of multiples of 40.

```

157 \def\XINT_mod_ccclx_i #1.% input <k>.<N>. k is a non-negative exponent
158 {%
159   \expandafter\XINT_mod_ccclx_e\the\numexpr
160   \expandafter\XINT_mod_ccclx_j\the\numexpr1\ifcase#1 \or0\or00\else000\fi.%
161 }%
162 \def\XINT_mod_ccclx_j 1#1.#2.% #2=N is a non-negative mantissa
163 {%
164   (\XINT_mod_ccclx_ja {++}#2#1\XINT_mod_ccclx_jb 0000000\relax

```

#2 will be empty in the "integer branch". Notice that a single dot "." is valid as input to the xintfrac macros. During developing phase I did many silly mistakes due to wanting to use too low-level interface, e.g. I would use something like #2[-\XINTdigits] with #2 the fractional digits, but there maybe some leading zero and then xintfrac.sty will think the whole thing is zero due to the requirements of my own core format A[N]....

The "userefunc" auxiliary macros do not pre-expand their arguments (but the macros which end up used in other ones defined from \csbxintdeffunc do).

Multiplication is done exactly but anyway currently float multiplication goes via exact multiplication after rounding arguments ; as here integer part has at most three digits, doing exact multiplication will prove not only more accurate but probably faster.

380                                0,
381                                tand(90-x*oneRadian))
382                                );%
```

12.12 sec(), secd(), csc(), cscd()

```
383 \xintdeffloatfunc sec(x) := inv(cos(x));%
384 \xintdeffloatfunc csc(x) := inv(sin(x));%
385 \xintdeffloatfunc secd(x):= inv(cosd(x));%
386 \xintdeffloatfunc cscd(x):= inv(sind(x));%
```

12.13 Core routine for inverse trigonometry

Compute asin(x)

The approach I shall first describe (which is only a first step towards our final approach) converges quintically but requires an initial square root computation. For atan(x), we do not have to do any such square root extraction. See code next.

The algorithm (for this first approach): we have $0 \leq t < 0.72$, let $t_1 = t*(1+t^2/6)$. We also have $u = \sqrt{1 - t^2}$. We seek $a = \text{Arcsin } t$ with $t = \sin(a)$.

Then $t_1 < \text{Arcsin } t$ and the difference (we don't know it!) δ_1 is < 0.02 . We compute $D = t*\cos(t_1) - u*\sin(t_1)$. This computation is done "exactly" via the `\xintexpr` encapsulation. In other terms we use doubled precision. Anyhow, currently (1.3e) the Float macros of `xintfrac.sty` for multiplication do go via such exact multiplication when the mantissas have the expected sizes. So we can't gain but only lose due to catastrophic subtraction in using float operations here.

Thus D is $\sin(a-t_1) = \sin(\delta_1)$. And $\delta_1 = \text{Arcsin } D$, but D is small! We then use again two terms of the Arcsin series and define $t_2 = t_1 + D * (1 + D^2/6)$. Let $\delta_2 = a - t_2$. Then δ_2 is of the order of the neglected term $3*(\delta_1)^5/40$.

©copyright J.F. Burnol, March 30, 2019. This surely has a name.

The algorithm is quintically convergent. One can do the same to go from exp to log. Basically the idea is that we can improve the Newton Method for any function f for which knowing target value of f implies one also knows target value of its derivative. In fact I obtained the quintic algorithm by combining the Newton formula with the one from using $f(x)/f'(a)$ and not $f(x)/f'(x)$ in the update to cancel the two quadratic errors.

@copyright J.F. Burnol, April 5, 2019. This surely has a name.
 Certainly I can do similar things to compute logarithms.

```

387 \xintdeffloatfunc asin_aux(X) := 1
388 \ifnum\XINTdigits>3 % actually 4 would achieve lulp in place of <0.5ulp

```

416 \xintdeffloatfunc acos(t) := Piover2 - asin(t);%
417 \xintdeffloatfunc acosd(t):= 90 - asind(t);%
    
```

12.16 atan(), atand()

This involves no square root!

TeX hackers note 1:

The `subs(, x = ..)` mechanism has no utility in a function definition, there is no parallel mechanism at the underlying macros, so in fact the substituted things will remain unevaluated if they involve indeterminates, so this is exactly like not trying to make things more efficient at all.

Currently, the only way is thus to employ auxiliary functions like is done next. Contrarily to TeX macros, we must define the functions one after the other in the correct order, so the auxiliaries come first.

TeX hackers note 2:

The `if(,,)` and `ifsgn(,,)` tests when used numerically compute all ; but when used into a `\xintdeffloatefunc`, they are converted to macros with basically `\firstofthree`, `\secondofthree`, `\thirdofthree` behaviour so then only the actually executed branch will do computations.

For numeric computations the `?` and `??` operators are used for this effect, but they can not be used in `\xintdeffloatefunc` if the test involves unknown variables; as explained above fortunately then `if(,,)` and `ifsgn(,,)` work.

radians

```
418 \xintdeffloatefunc atan_b(t, w, z):=%
419   0.5 * if(w< 0, Pi - asin_a(2z * t, -w*z), asin_a(2z * t, w*z));%
420 \xintdeffloatefunc atan_a(t, T) := atan_b(t, 1-T, inv(1+T));%

423   0.5 * if(w< 0, 180 - asind_a(2z * t, -w*z), asind_a(2z * t, w*z));%
424 \xintdeffloatefunc atand_a(t, T) := atand_b(t, 1-T, inv(1+T));%
425 \xintdeffloatefunc atand(t):= ifsgn(t,-atand_a(-t, sqr(t)), 0, atand_a(t, sqr(t)));%
```

12.17 Arg(), atan2(), Argd(), atan2d(), pArg(), pArgd()

`Arg(x,y)` function from $-\pi$ (excluded) to $+\pi$ (included)

```
426 \xintdeffloatefunc Arg(x, y):=
427   if(y>x,
428     if(y>-x, Piover2 - atan(x/y),
429       if(y<0, -Pi + atan(y/x), Pi + atan(y/x))),
430     if(y>-x, atan(y/x), -Piover2 + atan(x/-y))
431   );%
```

`atan2(y,x) = Arg(x,y)` ... (some people have `atan2` with arguments reversed but the convention here seems the most often encountered)

```
432 \xintdeffloatefunc atan2(y,x) := Arg(x, y);%
```

`Argd(x,y)` function from -180 (excluded) to $+180$ (included)

```
433 \xintdeffloatefunc Argd(x, y):=
434   if(y>x,
435     if(y>-x, 90 - atand(x/y),
436       if(y<0, -180 + atand(y/x), 180 + atand(y/x))),
437     if(y>-x, atand(y/x), -90 + atand(x/-y))
438   );%
```

`atan2d(y,x) = Argd(x,y)`

```
439 \xintdeffloatefunc atan2d(y,x) := Argd(x, y);%
```

`pArg(x,y)` function from 0 (included) to 2π (excluded) I hesitated between `pArg`, `Argpos`, and `Argplus`. Opting for `pArg` in the end.

```
440 \xintdeffloatefunc pArg(x, y):=
441   if(y>x,
```

```

442     if(y>-x, Piover2 - atan(x/y), Pi + atan(y/x)),
443     if(y>-x, if(y<0, twoPi + atan(y/x), atan(y/x)),
444           threePiover2 + atan(x/-y))
445     );%

```

`pArgd(x,y)` function from 0 (included) to 360 (excluded)

```

446 \xintdeffloatfunc pArgd(x, y):=
447     if(y>x,
448         if(y>-x, 90 - atan(x/y)*oneRadian, 180 + atan(y/x)*oneRadian),
449         if(y>-x, if(y<0, 360 + atan(y/x)*oneRadian, atan(y/x)*oneRadian),
450               270 + atan(x/-y)*oneRadian)
451     );%

```

12.18 Synonyms: `tg()`, `cotg()`

These are my childhood notations and I am attached to them. In radians only. We skip some overhead here by using a `\let` at core level.

```

452 \expandafter\let\csname XINT_flexpr_func_tg\expandafter\endcsname
453     \csname XINT_flexpr_func_tan\endcsname
454 \expandafter\let\csname XINT_flexpr_func_cotg\expandafter\endcsname
455     \csname XINT_flexpr_func_cot\endcsname

```

12.19 Let the functions be known to the `\xintexpr` parser

See `xint.pdf` for some explanations (as well as code comments in `xintexpr.sty`). In fact it is this context which led to my addition at 1.3e of `\xintdefefunc` to the `\xintexpr` syntax.

```

456 \xintFor #1 in {sin, cos, tan, sec, csc, cot,
457               asin, acos, atan}\do
458 {%
459     \xintdefefunc #1(x) := \xintfloatexpr #1(sfloat(x))\relax;%
460     \xintdefefunc #1d(x):= \xintfloatexpr #1d(sfloat(x))\relax;%
461 }%
462 \xintFor #1 in {Arg, pArg, atan2}\do
463 {%
464     \xintdefefunc #1(x, y) := \xintfloatexpr #1(sfloat(x), sfloat(y))\relax;%
465     \xintdefefunc #1d(x, y):= \xintfloatexpr #1d(sfloat(x), sfloat(y))\relax;%
466 }%
467 \xintdefefunc tg(x) := \xintfloatexpr tg(sfloat(x))\relax;%
468 \xintdefefunc cotg(x):= \xintfloatexpr cotg(sfloat(x))\relax;%
469 \xintdefefunc sinc(x):= \xintfloatexpr sinc(sfloat(x))\relax;%

```

Restore used dummy variables to their status prior to the package reloading. On first loading this is not needed naturally, because this is done immediately at end of `xintexpr.sty`.

```

470 \xintFor* #1 in {iDTVtuwxyzX}\do{\xintrestorelettervar{#1}}%

```

13 Package [xintlog](#) implementation

Contents

13.1	Catcodes, ε -T _E X and reload detection	407
13.2	Library identification	408
13.3	Loading of poormanlog package	408
13.4	The log10() and pow10() functions	408
13.5	The log(), exp(), and pow() functions	409
13.6	<code>\poormanloghack</code>	409

I almost included extended precision implementation for 1.3e but was a bit short on time; besides I hesitated between using poormanlog at starting point or not. For up to 50 digits, it would help reduce considerably the needed series for the logarithm. For more digits I should rather apply my copyrighted method of the arcsine (it must be in literature).

13.1 Catcodes, ε -T_EX and reload detection

Attention to catcode regime when loading below *poormanlog*. It (v0.04) uses ^ with its normal catcode but `\XINT_setcatcodes` would set it to letter.

This file can only be loaded from *xintexpr.sty* and it restores catcodes near its end. To play it safe and be hopefully immune to whatever is done in *poormanlog* or in *xinttrig.sty* which is loaded before, we will switch to standard catcode regime here.

As I learned the hard way (I never use my user macros), at the worst moment when wrapping up the final things for 1.3e release, `\xintexprSafeCatcodes` MUST be followed by some `\xintexprRestoreCatcodes` quickly, else next time it is used (for example by `\xintdefvar`) the `\xintexprRestoreCatcodes` will restore an obsolete catcode regime...

13.2 Library identification

```

47 \xintexprSafeCatcodes\catcode`_ 11
48 \XINT_providespackage
49 \ProvidesPackage{xintlog}%
50 [2019/09/10 v1.3f Logarithms and exponentials for xintexpr (JFB)]%
```

13.3 Loading of *poormanlog* package

Attention to catcode regime when loading *poormanlog*. It matters less now for 1.3f as those chunks of code from *poormanlog.tex* v0.04 which needed specific *xintexpr* like catcodes got transferred here anyway.

```

51 \ifdefined\RequirePackage
52 \RequirePackage{poormanlog}%
53 \else
54 \input poormanlog.tex
55 \fi
```

`\XINT_setcatcodes` switches to the standard catcode regime of *xint*.sty* files. And we need the *xintexpr* catcode for ! too (cf `\XINT_expr_func_pow`)

See the remark above about importance of doing `\xintexprRestoreCatcodes` if `\xintexprSafeCatcodes` has been used...

```

56 \xintexprRestoreCatcodes\csname XINT_setcatcodes\endcsname\catcode`\! 11
```

13.4 The `log10()` and `pow10()` functions

The support macros from *poormanlog* v0.04 `\PoorManLogBaseTen`, `\PoorManLogPowerOfTen`, `\PoorManPower` got transferred into *xintfrac.sty* at 1.3f.

```

69 \expandafter\let\csname XINT_flexpr_func_pow10\expandafter\endcsname
70   \csname XINT_expr_func_pow10\endcsname

```

13.5 The log(), exp(), and pow() functions

The log10() and pow10() were defined by `poormanlog v0.04` but have been moved here at `xint 1.3f`. The support macros are defined in `xintfrac.sty`.

```

71 \def\XINT_expr_func_log #1#2#3%
72 {%
73   \expandafter #1\expandafter #2\csname.=%
74   \XINT:NEhook:one\xintLog{\XINT_expr_unlock #3}\endcsname
75 }%
76 \def\XINT_flexpr_func_log #1#2#3%
77 {%
78   \expandafter #1\expandafter #2\csname.=%
79   \XINT:NEhook:one\XINTinFloatLog{\XINT_expr_unlock #3}\endcsname
80 }%
81 \def\XINT_expr_func_exp #1#2#3%
82 {%
83   \expandafter #1\expandafter #2\csname.=%
84   \XINT:NEhook:one\xintExp{\XINT_expr_unlock #3}\endcsname
85 }%
86 \def\XINT_flexpr_func_exp #1#2#3%
87 {%
88   \expandafter #1\expandafter #2\csname.=%
89   \XINT:NEhook:one\XINTinFloatExp{\XINT_expr_unlock #3}\endcsname
90 }%

```

Attention that the ! is of catcode 11 here.

```

91 \def\XINT_expr_func_pow #1#2#3%
92 {%
93   \expandafter #1\expandafter #2\csname.=%
94   \expandafter\XINT:NEhook:twosp
95   \romannumeral`&&\XINT_expr_unlock #3,!\PoorManPower
96   \endcsname
97 }%
98 \let\XINT_flexpr_func_pow\XINT_expr_func_pow

```

13.6 \poormanloghack

With `\poormanloghack{**}`, the `**` operator will use `pow10(y*log10(x))`. Same for `^`.

```

We don't worry about resetting catcodes now as this file is theoretically only loadable from `xintexpr.sty` itself which will take care of the needed restore.
